Well, my parallel-port code allows a lot more flexibility than necessary
in choosing R and P modulus values. In practice these two constants
will be fixed, eliminating a lot of the math that the PC code is doing.

With the LMX2326 (unlike the ADF4112), P is fixed at 32, so the minimum
supported N modulus is 992 (=P^2-P for any dual-modulus prescaler). In
general you want to minimize N for less reference-noise multiplication,
although at higher comparison frequencies the phase detector chip's own
noise starts to dominate.

At the time I was experimenting with the LMX2326, I was using an 11.5
MHz crystal filter on the reference, so the R value choice that
minimized N was 12 (Fc=958 kHz, N=1043 at 1 GHz). This is the R value
that yielded all of my best plots. By the same reasoning, the R value
for the 10.7 MHz filter we're using will be 11.

If you treat R as a constant, then the target comparison frequency can
be precalculated as a constant as well. Almost all of the math in my
SYNTH_calc_DDS_frequency() function can be calculated offline with
knowledge of DDS_CENTER_FREQ (=10.7 MHz), R (=11), and FOUT_MIN (=1
GHz):

```
center_comparison_freq = DDS_CENTER_FREQ / R =972727
min_N = FOUT_MIN / center_comparison_freq =1028
DDS_bw = center_comparison_freq / min_N * R =10408
```

DDS_min_freq = DDS_CENTER_FREQ - (DDS_bw / 2) =10694796
Fcomp = DDS_min_freq / R =972254

The first three expressions determine the required DDS tuning range in hertz. This range needs to remain safely above the comparator's detection threshold as it passes through the crystal filter.

DDS_min_freq is simply the lower end of the DDS tuning range, based on the DDS bandwidth previously calculated.

Fcomp is the comparison frequency that, for any output frequency that's an exact multiple of N, corresponds to the lower end of the DDS tuning range.

At runtime, Fcomp is the only result we need. This is the "target" PLL comparison frequency that will be used to determine both N (for the PLL) and DDS_freq (for the DDS):

N = output_freq / Fcomp
DDS_freq = output_freq * R / N

That's it... those two are only two equations that the microcontroller needs to solve when changing frequencies. output_freq must be a 32-bit unsigned integer for 1 Hz resolution from DC to 4 GHz, and DDS_freq can be a 24.8 fixed-point value that will fit in 32 bits with a larger (32.8) temporary store for the (output_freq * R) / N calculation. Any microcontroller should be able to do this with no trouble at all.

The N calculation above is assumed to round by truncation, C-style. We must round N down to the next-lower integer because Fcomp was calculated based on the lower end of the DDS tuning range. If your math routines round differently, you'll have to walk back through the equations to make sure the DDS tuning range is still centered in the crystal filter's passband.

```
DataErase II ACT EPROM eraser:

four position, with timer, with wall adapter
asking $20

Miscellaneous MicroChip PIC parts and boards:

ProtoPIC boards (4)
for 18pin PIC
prototype array 14 x 15 holes
pins for regulator, caps, crystal or resonator
traces for SOIC EEPROM and motor controller
two boards have socket, regulator, caps, and 4MHz
crystal
two boards are blank

Various PIC chips
2 16C54/JW-S1 windowed EPROM
1 16C55/JW-S1 windowed EPROM
1 16C71/JW-S1 windowed EPROM
2 16C54/RC-P OTP
2 16C55/RC-SP OTP

asking $20 for all the PIC parts and boards

Located west of Chicago; prefer local buyers; shipping extra.
And, yes, I'll regret it when they're all gone! :-/

Thanks!

While I'm a big fan of DigiKey, and I get all my PICs there, they don't satisfy one of Ed's requirements - no service charge for orders under $25.

Jameco does have PICs and I believe they don't have a minimum order. I think you can get a good deal on shipping through them, too, but I don't know that for sure. I rarely order from Jameco preferring DigiKey's outstanding service.

..

To tell the truth, I don't know where you can get a PIC

Likely what you say is true, I don't know.

What I had given some thought to is:

Use a microcontroller analog-to-digital input to
sample the Icom band data voltage.

Using the microcontroller, set the status of 4
digital discrete outputs to the Yaesu type band
data.

This could be done with a PIC, or simpler something
like the NetMedia BX-24 (an enhanced BS2 type thing
with A/D inputs etc).

For me, the microcontroller route would be simpler.

Source record: 46173

Hmmm... Input impedance of the Tayloe detector...

Well, in the typical application, it is working against the antenna input impedance of 50 ohms as part of the effective R/C lowpass effect. The actual impedance of the switching device is something like 2 or 3 ohms so the antenna reactance is a major part of the lowpassing.

Which means that the lowpass frequency rolloff which occurs in the capacitors to ground after the switching device will vary depending on the antenna impedance. It can be a major change. For example, if one goes from a resonant antenna to a random length wire.

If using an RF preamp then depending on the design of the preamp, it may provide a fixed impedance into the detector but even so the lowpass is a function of the impedance of the RF amplifier and not the switching device.

Some of the articles I've read mention 200 ohms, but that is the result of the 50 ohm resonant antenna being connected to a given capacitor 1/4 of the time, hence 200 ohms effective impedance.

So if you have an off-resonance antenna, say for a multiband Rx of some sort, the antenna may be, let's say 200 ohms, then that is multipled by that 1/4 multiplexing on interval and the tayloe detector is now forming a lowpass with effectively 800 ohms resistance working against the shunt capacitor to ground.

For that sort of general use, you have to make the capacitor small enough so that the lowpass rolloff won't bother the desired audio band even under the worst case antenna you are willing to allow.

Which means that when you happen to tune the detector to some frequency where the antenna is resonant, the lowpass won't roll off very much.....

This means the detector works best in a narrow band, resonant antenna application, where you can set the integrating capacitors to cause lowpass rolloff just above the desired audio bandwidth.

One of the things that struck me when people first mentioned the "Tayloe
Mixer" here (and I found a schematic) was a certain resemblance to
the sort of circuitry used in Coherent CW. I probably noticed it
because looking at CCW schematics, there was something nagging me
at the back of my mind. There was something there that I thought could
be extended....

I've always been curious about how Dan Tayloe came to the circuit.
What prompted him to give it a try? I've not seen anything about
this (though perhaps I missed it). Because seeing commutating filters
(the first issue of QST that I ever saw, April 1971, had such a filter)
and seeing those CCW schematics made me think, though I never tried
anything and there was only supposition (and vague enough that I can
no longer remember exactly what).

In CCW, you have two data paths. In each, there is a mixer (or was
it a sample and hold?) being clocked at the input frequency, but
the clock to each channel is in quadrature. So you get a DC signal.
You then have two more mixers (or again was it a sample and hold?),
clocked at audio frequencies. Again, the clocking is in quadrature.

It's been a while since I've looked at descriptions (and sadly, none
of my books have CCW in more than passing), but the first conversion sure
looked like what you'd see in a phasing receiver. The second conversion,
back to audio, seemed to do the job of the audio phase network, The
result was singal signal, but a narrow bandwidth.

The best article in the ham magazines about commutating filters was in Ham
Radio magazine, circa 1978, I think by Hank Olson. Unless I'm garbling
it, the cover features Wes Stewart's split-band voice processor. I
had always meant to dig up some of these articles and post a bibliography,

because of the similarity between commutating filters, and CCW, and the Tayloe Mixer.

I think you misunderstood the setup which is difficult to explain in text.
The filter effect works at RF
For example, on a breadboard test with a clock of 3.5 MHz, the ouput peaked with an input frequency of 3.5 MHz (ie at the clock frequency) and with some setups (eg having an input resistor to increase the R in the RC network) a very sharp peak could be obtained (6 dB down at inputs of 3.5 MHz +/- 20 KHz or so)
Moreover the filter can be tuned to any frequency simply by tuning the first mixer clock. Further filtering can be performed by making the second multiplexer clock at some IF (say 455 KHz) and the signal is then upconverted from zero to 455 KHz without image problems. (apart from "inband" images due to quadrature/SSB inbalance)

Actually what got me started in this direction was the availability of
the TI 74CBT3253 high speed analog mux and a 3000 mile (Phoenix to New
York) cross country drive. I had lots of time to do nothing but think
and ponder. The 74CBT3253 is a zero delay analog mux (as opposed to a
high delay digital gate) used to connect microprocessor address and data
lines to different banks of memory. It was never intended for analog
use, but it works quite well for that task.

I knew about audio switched capacitor filters using an input resistor
and four capacitors which were switched at a 4x rate. The input side to
the mux ends up exhibiting sharp bandpass behavior, based upon the R/C
time constant of the single R and multiple Cs used.

The idea of an active RF bandpass filter on a receiver front end is what
got me started. Since we now had a *really* fast dual 4:1 mux part,
perhaps I could do some active RF bandpass filtering using the switched
capacitor filter in front of a receiver mixer rather than a simple fixed
tune bandpass L/C.

The really neat thing about this is that if I combined the VFO and IF
BFO signals together at a 4x rate, this narrow active RF bandpass filter
would track the receiver tuning. This should enhance receiver
performance on congested bands such as 20m (contests) or on 40m with big

adjacent SWBC signals.

I pondered this and the fact that if I was using a really narrow rf active filter, the signal I really wanted was at an offset of 600 to 800 Hz, and if I tried to do 4x at that offset frequency, I would likely be injecting a really strong signal on top of what I wanted to listen to. I pondered this aspect quite a bit.

In order to produce the necessary 4x clocking for the rf switched capacitor filter, it would be necessary to combine the BFO and VFO together and then produce a composite 4x signal (maybe using a PLL or a bunch of exactly synchronized DDSs... a bit complex but manageable) to drive the filter.

In order to simply test the idea, I decided upon a scheme to use a direct conversion receiver as the test bed. Then it would be simple since the 4x signal used for the RF switched capacitor filter could be divided by four and used for the direct conversion mixer VFO.

Much simpler! A direct conversion receiver would not be optimum, but it would allow me to test the idea before trying the more complex 4x clocking trick on a superhet receiver.

It was then that I started thinking (I was still driving) about what the signals looked like on the switched capacitor filter at zero beat to an incoming RF signal, which would be four equidistant points on a sinewave, stationary. Then I thought about what they looked like when not exactly on frequency: each of the four outputs would drift slowly tracing a sinewave at the difference frequency, each formed of RF samples taken 1/4 cycle apart, each output then being 90 degrees apart from each other.

I suddenly realized that the switched capacitor topology could be used as a detector (no separate direct conversion mixer required), that it naturally produced all four phases of output, had bandpass characteristics, and that the input RF signal was being "integrated" on to each of the four capacitors through the input filter R, so that only difference frequency appeared and not the sum. Lastly, I realized that the new detector seemed to capture the peak RF voltage, and thus have a low detection loss (under 0.9 db conversion loss).

Since I have read about the R2 phasing receiver, I began to work on receiver designs based upon that approach (two branch I and Q audio combined using 90 degree phasing shifting to given single sided reception). I have been working on incrementally making improvements to the basic design for several years now. I am on my 4th generation design, and there are still ideas to try out and improvements to made. I am trying out new modifications this weekend.

I never returned to pursue the RF active front end receiver filtering aspect. There is only so much time in the world to experiment! It might not work the first time, but problems are simply engineering opportunities.

It is true that the performance will vary according the source impedance of
the circuit
We have used a preamp with a predictable input impedance - eg a grounded
gate FET circuit whose input impedance is proprtional to Gm*drain current.
I am not sure what this looks like as a source to the mixer however.
Presumably the best circuit would be a low impedance source for the mixer
with the filter R in the RC set by an input resistor to the mixer.

At this point the circuits are similar

So you get a DC signal.
> You then have two more mixers (or again was it a sample and hold?),
> clocked at audio frequencies. Again, the clocking is in quadrature.

This is equivalent to the second multiplexer except that in our circuit the
second clock converts from DC back up the signal frequency or to some IF. In
the CCW case the IF is at audio (but not 0Hz). Presumably this has the
effect of shifting the CW carrier by an amount equivalent to the second
clock

Dear OM

A friend of mine has a broken Kenwood TL-922 amp. The faulty part is the transformer of the power supply ("T2", according to service manual), we can tell and smell from the smoke coming out of it.
The Belgian Kenwood service center does not have this part available anymore, and according to them, both the stocks for this spare part in the USA as well as Japan are exhausted.
Now, my question is: does anyone know where to find this part, and if there is a manufacturer of equivalent transformers to replace it?

All help would be greatly appreciated!

I'm not an expert on such circuits but I beleive that a switched capacitor filter will respond at the clock frequency, and at harmonics of the clock frequency. If the input signal is less than half the clock frequency you can use it as a low pass filter, with a rather sharp cut-off, if I can recall correctly.

What is usually done is to put an analog filter before the thing, allowing you to select which 'mode' you want it to work in.

Ouch. (my AL-80A suffered a similar problem though luckily without smoke!)

Has he tried Peter Dahl http://www.pwdahl.com ? They've got a pretty wide
variety of transformers for amateur amplifiers. (I do wonder if it's less
expensive to buy a new amplifier than to pay the shipping charges to have a
plate transformer shipped from Texas to Belgium?!<grin>)

Thanks Rex, and Mark. I've ussed DigiKey a lot in the past, but now
that I'm retired and trying to stay on a limited mad-money budget, I'm
much more sensitive to minimum orders and S&H charges. If I need
something that runs over $25 then I'll usually go to DigiKey first.
Otherwise I'll try Newark, Pioneer, or RadioSahck.com.

Jameco certainly looks promising, I haven't ordered anything from them
in a long time.

Thanks again,
Ed

Hi Paul, try this URL:

http://rf.rfglobalnet.com/software_modeling/categories/2.htm

Download tunekit.zip which is a simple program to design coupled LC resonator narrowband filters. For a 123MHz center freq., BW=10MHz, the resonators are about 80pF and 17nH, coupled with approx. 4 pF caps. It also tells you how to make the coils. You'll probably have to tweak the 80pF caps for flat response no matter what.

There is some other software at that site which might help.

I have some info copied which would allow you to derive the values if you want to email me at aa1ll@email.com.

Jim
I guess the Tayloe circuit could be looked at as a quadrature switched capacitor filter
So the source of some of our noise may be Audio getting through the Tayloe detector
Perhaps we should put an analogue high pass filter in front of the first set of mixers

Richard

amother friend (LA7MI) mentioned that it wasn't a new idea, it is
mentioned in VCO catalogue from Mini-Circuits

Any impedance will improve, but it is some different opinions whether
it is wise to let the transistor saturate, the gain will also be lower
and effective capcity lower.

Such capacity multiplication is also used in Drake R-4C receiver +12V
power supply, but consumed lot of power since it was current fed from
+125V

"JLB" wrote ...
> Don't mean to get testy here, but my question was about using
> ***Visual Basic*** from ***inside Excel***, not C++!!!

Have you never learned to translate interface specs from C++ to VB? If not, then you will have a very difficult time trying to use VB for any but the most mundane tasks. Most of the interesting parts of computing are documented in C++. That doesn't mean that people USE that language, it is merely a standardized format.

For example virtually all of the API (application program interface) in MS Windows is documented in C++ even though it is used by tens of thousands of VB programmers and programs. There are resources out there that help "translate". The MSDN library is very helpful. However I'm pretty sure the basic info is available free on the MS web.

If you mean "Visual Basic for Applications" (VBA) (your reference "inside Excel"), it wouldn't surprise me if this were impossible. I don't believe VBA is powerful/rich/flexible enough to interface directly to IO hardware. VBA is an application scripting language and is a limited subset of the "real" version.

In that case, Ms. Halliday's suggestion of parsing a WAV file is probably your only practical solution. Information on WAV file format is also readily available on the web. I would suspect that you COULD write VBA code that would parse WAV format.

This is a really old circuit. I has been used in power supplies long before the zener diode became a common component. A series pass transistor with a low resistance resistor from collector to base would drive the transistor into saturation, however, adding a big capacitor from base to ground will create a RC network followed by an emitter follower.

Or looking at it differently, during the peaks of the rectified 100/120Hz ripple, some of the current is required to charge the capacitor, thus preventing the transistor from going into saturation. During the low parts of the ripple, the capacitor will supply most of the base current to the transistor, possibly driving it into saturation.

I think this circuit was called a capacitance multiplier, since the ripple rejection was similar to a big capacitor with a capacitance equivalent to the real capacitor multiplied by the current gain of the transistor. Thus with a real 220 uF capacitor, you could get a 22000 uF virtual capacitor if the transistor beta was 100.

Unfortunately some misunderstood this circuit and thought that they could get away with the big storage capacitor and only use this virtual capacitor :-). However, when the collector voltage drops below the capacitor voltage on the base during the bottom of the ripple cycle, the transistor no longer conducts and the charge within the small capacitor is quickly discharged though the base-emitter diode and the load and the voltage drops very quickly.

This kind of circuit disappeared very quickly when the zener diode become popular.

The idea of using this circuit as a low noise oscillator power supply postregulator is very interesting since a small, low inductance, low ESR capacitor could be used, thus, you could have a nearly ideal 100-300 uF virtual capacitor.

However, what is the point of driving the transistor into saturation ? This will reduce the current gain and thus reduce the size of the virtual capacitor. Keeping the transistor in the linear region by limiting the base current below saturation will require a larger Vce voltage drop. If the load current varies, limiting the base current below saturation will also affect the voltage regulation, but this can be partly compensated with a resistor from base to ground as was done in some early designs.

I need at least one more PYE 19" rack cabinet to match the 2 I already have. Size is 49cm wide, 30.2cm high and 30.8 cm deep (not measuring the back panel that sticks out another 7 cm). Says, "PYE Communications Equipment" at front of cabinet. Ventilation grill covers backhalf of top panel. Be particularly nice if any source is say 30 miles of Wakefield in West Yorkshire, (but perhaps unlikely).

I suppose if you have a cabinet it may contain some older PYE/PHILIPS gear. I'd buy that if cheap (just to get the cabinet!!). Thanks. Rich.

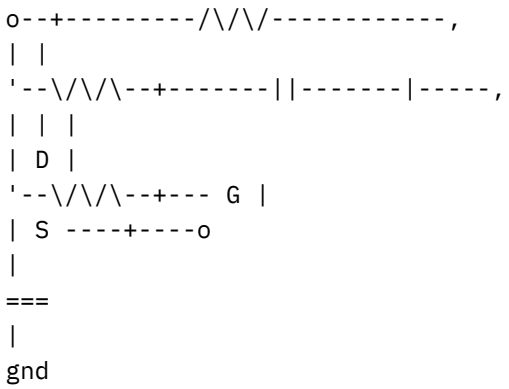
The circuit you describe has a drop of Vbe + R*Ib, which may be closer to 1.0V than to 0.1 or 0.2V as Jan-Martin describes. Jan-Martin must be thinking of a pnp transistor with its emitter as the input, hence the saturated operation. Offhand, I don't see how such a scheme could reduce ripple. The active filter you describe Paul on the other hand works very well. Of course the transistor base-voltage point must be low enough not to get C-E saturation from the ripple valleys at maximum load, but this is easily done by adding a resistor to ground. For high-voltage supplies I like to use a MOSFET and thereby get an instant 3 to 4V drop, usually solving the problem, while allowing much higher R and even a smaller C.

Another very useful enhancement is to divide the input resistor in two and filter that node with a capacitor to the quieted follower output. This creates a 2-pole filter which further reduces the output ripple, especially the sharply-rising charging edge which is highly attenuated by the -12dB/octave rolloff.

As for this circuit disappearing quickly when the zener diode became popular, hah! the zener has been with us for far longer than the BJT power transistor, it was the power IC regulator which supplanted this circuit. However I still use it for the common case where I want all the output voltage that's practically available from the supply storage capacitors, and simply want to eliminate any ripple noise.

The main thing it lacks is current-limiting, but I solve this by adding a series collector (drain) resistor sized to drop 0.5 to 1V under normal load. This resistor saturates the transistor upon a load fault, so that no heat sink is required on the pass transistor. Of course this resistor

itself must have a serious power rating (or one may be happy to let it to go up in smoke, protecting the pass transistor!).



A further enhancement is to add an output current-sense resistor plus a small current-limiting transistor, plus two more resistors to create a foldback current limit, solving the smoking-resistor problem. At this point a heat sink will no doubt be required for the transistor. A gate protection zener may be a good idea for the MOSFET. It's at this point that one looks at all the parts drawn on the sheet of paper and begins to reconsider a simple IC regulator, with built-in thermal limiting.

:-)

1568. Re: 10.7 Mhz IF and HF

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-23 19:47:32 UTC
From: Peter Rachow <peter.rachow@t-online.de>
Message-ID: <a58ri8lbm02$1@news.t-online.com>
Source record: 46110

Paul,

the higher you choose your IF, the fewer problems you will face with the so called "image" frequency. This the second frequency that you're always receiving unwantedly with a superhet. Due to the fact that your superhet receives f1 + f2 *and* f1-f2 you will hear two signals.

Calculation sample:

fRX = 14.100 MHz
fIf = 455 kHz
required fOsz. = 14.555 Mhz

Image frequency = 14.100 MHz - 0.455 kHz = 13.645 MHz

So your superhet theoretically is able to receive 2 separate frequencies. The higher your if is the more the unwanted signal will be filtered by your input selective circuits (LC-filters) becaus the band distance doubles with each kHz the if is higher.

Next Problem: A high if requires good IF-filters, because it is not so easy to filter high frequencies with standard LC-circuits (as they are common for 455 kHZ). Therefore crystal filters are commonly preferred here. A double superhet sometimes is a good solution but has a seriuos shortcoming: More self generated intermodulation products that are falling into the received band.

hth es 73!

Peter

Source record: 46111

Peter explained it pretty well, I think.

But better receivers today typically have 3 IFs ... usually the first is in the 60 MHz range. I'm not so sure I know why that is. The second is generally in the 10 MHz neighborhood, and the third is typically 455 or so.

Peter explained why a first IF of 455 is a problem. It's tough to get good image rejection at that frequency. But there is another side to the problem that makes the 10 MHz IF a problem. While crystal filters are possible, and even necessary in many cases, for a 10 MHz IF, getting the right shape can be a problem. This is especially a problem for SSB on the ham bands, where you need a nice flat passband with steep skirts. It's much easier to make this sort of filter for a low IF than for a high. So many receivers use a 10 MHz (or so) IF to get rid of signals that are a little way from the desired signal, as well as images, then the 455 to whack out the close in interference.

This is less of a problem for CW. On CW, you really don't need the flat passband, a pointy-topped filter is pretty acceptable. This is easy to get by stringing together a few matched crystals. So many receivers intended for CW only have only a single IF, typically in the 10 MHz neighborhood, with a multipole crystal filter that gets you both image and near signal rejection.

It would seem like the availability of parts for 10.7 MHz IF's would make that a popular frequency. However, what is available is often for FM receivers that need a very wide passband, so selecting 10.7 specifically really doesn't turn out to be a big advantage. As a result, frequencies like 10, 9, and 4.9152 are a lot more popular for amateur band receivers.

..

Saves money on front-end filtering. With (say) a 75-105 MHz LO and 70 MHz 1st IF, a fixed low-pass filter is enough to handle the whole HF spectrum without any image responses. No preselection required.

Of course, VHF local oscillators are almost inevitably noisier than HF ones, so reciprocal mixing can be a problem. And without any preselection at all, you need a much stouter mixer with more LO drive to keep IMD under control. No free lunches in the radio business!

And, more to the point, why doesn't anyone sell a low-noise 3-terminal regulator? The old-school LM723 is not a very elegant solution considering the number of pins and amount of support circuitry that chip requires.... yet it still seems to be the only game in town for low-noise regulation.

The ARRL has recently reaffirmed just one week after the original historic announcement (08-Feb-2002) that eQSL Cards - ARE - accepted for DXCC....this remark from the eQSL Webmaster found at this

URL: http://www.eqsl.cc/qslcard/comments.cfm
"ARRL reaffirmed today that it will accept eQSLs that are mailed. AG or not" (Webmaster)

> What are the pros and cons compared to 455Khz ? Any response
> appreciated. Thanks.
>
> paul@paulrowe.com

At this point in time, I think you'd rather go with an IF in
the MHz range, unless there was a specific reason not to. Remember,
that 455KHz IFs date from when it was easier to go low in frequency
to get the required bandwidth, and when crystal filters in the HF range
came along, they gave the needed bandwidth. And you benefitted from
much better image rejection. If you read reviews of low end shortwave
receivers from the sixties, they'll often note very low image rejection
on the highest band. Going to an HF range IF means you don't have
to put a lot of effort into the front end in order to reduce the image
sufficiently.

Some people will say that a Collins mechanical filter which would be
at 455Khz or 500KHz, are a better choice than a crystal filter. But
at this point in time, you'd want to go with a double conversion scheme,
which is what's happening in commercial receivers that still use 455KHz
IFs. In those, the low IFs are often for some extra feature, like
passband tuning, where the added conversion is already needed.
(Note that most consumer AM broadcast band receivers and low end
Shortwave receivers still use 455KHz IFs, and one can assume that
it's due to reasons of economics. Certainly enough time has been put
into designing AM BCB receivers, so they know how to work around the
image problem, and 455KHz is such a common IF that ceramic filters
are plentiful for AM-bandwidth.)

One significant problem of an IF in the HF range is that if the receiver
is general coverage, you'll have a hole in the coverage. You're going
to have problems with reception right around the IF. But if you are
only covering some segments of the HF range, such as the hambands,
then an HF range IF gives you better image rejection, and an easier
design.

Nowadays, a lot of receivers have the first IF above the HF range, so
there isn't that hole in the tuning range. Of course, these tend to
be general coverage receivers. The disadvantage is that you need
a much higher local oscillator frequency for that first mixer,
and so there'll be complication there.

Unless you are just using the 10.7MHz IF as a first IF, and a second conversion to some other frequency for ultimate selectivity, you might want to reconsider the frequency. I don't think there is a wide selection of filters on that center frequency. Most common, you'll find FM-bandwidth filters, which would only be useful for FM. Certainly you're more likely to find AM, SSB and CW bandwidth filters at 9Mhz than 10.7.

(And they are likely to be expensive, unless you can find surplus filters. That is an advantage of 455KHz (or the similarly used 450KHz); you can probably scrounge up a number of filters for less than doing the same in the HF range. Certainly AM-bandwidth filters are easy to come by, and I think you can find narrower filters in CB sets. For a good CW or SSB filter, you could find a used mechanical filter. So the choice of IF may depend on whether you can get by with one filter, or need different bandwidths.)

A lot of people seem to be building their own ladder filters, which seem to be easier to build than the old lattice filters from the early days of SSB. Since they depend on a good number of cheap crystals, the IF frequency is chosen because the crystals are available. For a ham band receiver, the exact IF frequency won't matter so long as it's not in a ham band, and you do some calculations to make sure don't end up with some weird response when the IF and local oscillator mix together.

Thread:

Failed transformers. In the "old days" we used to re-wind them. I've done
a few myself.

You loosen up the windings and insulation by burning it out with a blow
torch, then measure the wire size, un-wind it, re-insulate and re-wind it.

Remember to count the turns and make a drawing of the winding layups as you
unwind it...

It's fun... and you can often make it better than new.

It's obviously SPAM since it's followed up to all sorts of groups that don't
care!

Somewhere (I think it was on the eQSL site) I saw where you had to have the
card mailed from eQSL (at a buck a card). Seemed to me exactly like the
sort of thing the League would dream up. Still, a buck is better than 3
IRCs.

In any case, you're right. If it were the case, there would be something on
the ARRL site. The last mention I could see was a year ago where the league
was working with a software vendor to provide a secure eQSLing service.

What's the difference? Ain't nothin' "historical" about this announcement.
What the ARRL (may have) said is that they will accept the (e)QSLs that are
mailed. I fail to see the difference between a mailed QSL that had been
verified and printed by a QSL manager and a mailed eQSL that had been
verified and printed by the eQSL service.

1583. Adding high frequency roll-off to a set of stereo headphones

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-24 08:47:54 UTC
From: googlyelmo@earthlink.net
Message-ID: <3C78A8B7.D9AB7193@earthlink.net>
Source record: 46123

I want to cut the high-frequency response of a pair of mid-quality closed-cup stereo headphones I use for CW operating. I'd like to reduce the 'phones response above 8 KHz or so. I have used in the past true "communications" grade headphones with response cutting sharply off in the 7-10 KHz range, so I know what a tremendous benefit they can be for extended operating compared with phones made for listening to music with an 18-22 KHz upper cutoff. Much of the QRN, especially on 20 meters and above, is above 8 KHz. Getting rid of it is like dropping the weight of a backpack on an uphill hike.

I remember, dimly, reading somewhere that you can cut hi-freq. response by adding a capacitor across the two headphone leads. Am I correct in my recollection? If so, does the *type* of cap matter [i.e. ceramic, mylar, mica, etc.]? While I know that a bit of trial-and-error substitution probably will be involved here, what general value should I be looking at trying? Finally, exactly how should the cap be wired into the 'phone circuit? I think I remember reading that you simply solder one cap lead to each of the two phone wires, but please confirm/correct this. Thanks.

1584. HF transceiver miniature

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-24 09:26:09 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3c78b099$0$9073@echo-01.iinet.net.au>
Source record: 46124

Dear Group

I have a hankering to build a transceiver covering some (3-4) of the HF bands with the following specs
I have done one version for 40/20/18 which worked ok but only had 1W out and is fairly fragile

Physically small/portable for walking/backpack
Surface mount components
Reasonable strong signal handling
CW/SSB modes (not AM/FM)
components reasonably easily available/cheap!
Current drain low on receive
3-5W out

I would be interested in ideas re
(1) Topology
I am not keen on doing fancy DDS/DSP type solutions for portable use (even if I could!)
A conventional single conversion superhet seems like the best idea with an IF of ?10.7 MHz, with filter type SSB generator using a balanced diode/filter setup (simple and carrier suppression is not critical)

(2) important components
Power amp transistors
I thought I would use TO-126 GP transistors with a Ft of about 150 MHz - these are $2 or so from Digikey
Anyone done an HF amp with these?
Mixer
I am not sure what is available in SM
A TUF-1 from minicircuits would give reasonable SS handling but would require more LO drive
IF amp
The venerable MC1350 still seems not a bad choice but can you get it in SM?
Is there a better choice with AGC?
Filter
I thought I would use a conventional monolithic filter as a simple solution.
LO
I will use a free running VFO with crystal osc mixer/BPF for each band. The VFO will be stabilized by my counter/PLL module

I would be grateful for any feedback

Richard

1585. Randy Rhea's HF Filter Design Book

1586. Artificial antenna pad for BC-receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-24 12:34:11 UTC
From: la8ak.xnd@online.no
Message-ID: <3c782af7.258995765@news.online.no>
Source record: 46126

The handbook for my old BC-receiver recommends an "artificial antenna"
to be connected in series with RF signal when sweeping the AM section,
somewhat difference between Long- and Medium-Waves.

The pad consists of 220pF, 390pF, 390 ohm resisistor and a 22uH coil.

Does it mean that this pad should be inserted when I use an external
antenna like an active antenna with 50 to 75 ohm impedance?

From: "Carl R. Stevenson" <wa6vse-shack@fast.net>
Message-ID: <3c78f1a3_2@news7.fast.net>
Source record: 46127

Sounds to me like something very similar to, if not
effectively the same as, the Weaver modulator and
a LOT of other prior art which builds on the Weaver
modulator ... basically, mix (or sample, which is the
same thing, effectively) down to baseband, lowpass
filter, then mix back up to some other frequency ...
if the phases are arranged properly, it's "single signal"
(ssb) and the "LO" for the 2nd mix (back up from
baseband) can be arranged to make the recovered
signal fall at audio, thus making it a demodulator.

Source record: 46128

Hello Jan.....I'd have to say yes to your question on the assumption that the input to your BC receiver must be Hi-Z (What is the actual circuit for the pad?). Perhaps the manufacturer determined that the gain of the input RF amp or the 1st mixer operation might be influenced adversly by the Lo-Z source (a regen or TRF might have different/worse characteristics). Personally, I'd build the pad, then try it and compare feeding directly from your active antenna (with a look at the BC circuit first) - Of course if your active antenna is powered through the coaxial lead this might influence the decision :)

http://homepage.eircom.net/~ei9gq/amp-mod.html works very well
for me.

> (2) important components
> Power amp transistors

CB PA transistors - I don't know what they use in modern CB's,
The 2SC1969, 2SC1307 and 2SC1945 were popular choices in
the old days.

> Mixer
> I am not sure what is available in SM
> A TUF-1 from minicircuits would give reasonable SS handling but would
> require more LO drive

Sounds good. Check www.analog.com for IC mixers.

> IF amp
> The venerable MC1350 still seems not a bad choice but can you get it in SM?

The MC1350 is still available. I believe they are no longer in
production so stocks will dry up eventually. I think there is a SM
version but I've never seen one.

> Is there a better choice with AGC?

I don't like to recommend something I haven't tried myself but
have a look at the AD603. I have heard good reports about them
from some of the folks on the UK homebrew net (3.727MHz).

The National Semiconductor CLC520 is another one worth
looking at.

I have data-sheets for both, if you can't find them on the
web.

> Filter
> I thought I would use a conventional monolithic filter as a simple solution.

If you can find one at a reasonable price. Check Aleksander Stare's
web-page for some homebrew ladder filter designs. There is a link
on my page. See below.

> LO
> I will use a free running VFO with crystal osc mixer/BPF for each band. The
> VFO will be stabilized by my counter/PLL module

Sounds good. If you are using the usual 5-5.5MHz approach, a
DDS might be a better approach, especially for mobile use.

> I would be grateful for any feedback

thanks for your support. The active antenna is fed from 12V source in
the shack, but a divider is connected in between for signal to my
BC-receiver. It is lot of signal level so no problem to avoid thinking
about impedance matching. BBC Radio 4 on 198kHz has 500 V (-53dBm)
signal level in the evenings, and signal levels around 136KHz is far
above minimum receive level. Only problem is electrical noise, so a
balun (choke) of 9 turns of RG224 on ferrite toroid core is inserted
between the antenna and first divider.

I eventually made the pad with male and female BNC connectors on a
SUCO-box
IN-220pF--|-------22uH--|- OUT

1591. Re: Artificial antenna pad for BC-receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-24 17:30:26 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a5b92q$5vbjn$1@ID-124126.news.dfncis.de>
Source record: 46131

An artificial antenna is used when aligning the RF tuned circuits in a radio receiver. It is connected between the receiver input terminal and the signal generator.

Was most commonly used at the end of the assembly line in radio factories.

When a real antenna is used put the artificial antenna back on the shelf. It won't be needed again till the next realignment is due in 5 years time.

Old MW and LW valve receivers had a much higher input impedance than 50 or 75 ohms. Could be as high as 1000 ohms. But there was no standard impedance. It didn't matter.

The artificial antenna was designed to represent the average of all the millions of lengths of wire used as real antennas.

Which was any length between 1 metre hanging out the back of the set and 50 metres if the back garden was long enough.

Source record: 46132

From the circuit you posted it can be deduced the artificial antenna very crudely repesents an antenna wire about 100 feet = 30 metres long, with a poor ground.

Ground one end via a low impedance signal generator. Input impedance at the other end is intended to be typical of domestic radio receiving antennas, world-wide, in the 1930's and 40's. My father had a 25 metre wire throughout that period.

At VLF 220 pF is the capacitance of 100 feet of wire.

Above a few MHz 390 ohms is Zo of the wire considered as a transmission line.

The loss resistance slowly begins to increase around 150 KHz. Around 1 MHz the resistive component starts rising faster to account for a real antenna's radiation resistance.

We were talking about these before here.
http://dimensional.com/~melissa/mrf138.htm

Some people are asking $75-125 each for them.

But we could use a new hard drive and some software for the house, so if I wanted to sell them fairly soon, how much could I reasonably expect to get for them? Maybe $50 each if someone takes the whole lot of them?

I've been told my fellow hams are too cheap when it comes to this kind of thing, but they're the ones most likely to build things with these, right?

I've got a John Deere 140 (20 yrs old but good) garden tractor, mower. It's a 12 volt system and the rectifier regulator module is shot. They want nealry $100 for it, too much in my opinion. It's in a die cast aluminum case sealed with potting compound. I've tried several solvents, some for a week with no luck. The alternator on the tractor puts out about 30 volts AC at full speed so I guess there's a diode bridge and a series regulator to dump any excess. In addition I've not had any luck in chasing down a cirduit diagram but have found that a similar device is used on some Japanese motorcycles. The have problems too and are expensive. I see some reasonable priced rectifiers on this site;
http://www.aceelectric.com/PDF/BulletP/99Bull/99May.pdf but I've not been able to find any regulators. Does anyone have a diagram of a unit that works well or can point me to where I can look for a diagram, regulator, both or other complete units that are reasonably priced..
tnx

Hi,
I just purchased a Kenwood TS-2000 and am wondering the best way to key an SB-200/220 with the transciever. My old rig was TS-830S and this wasn't an issue. Searches on the web have been inconclusive. I am wondering if solid state is the way to go or just KISS and use a low milliamp coil 12V relay. Any help would be appreciated.

You can indeed cut the HF response by loading with a capacitance, but
for it to work as you expect, you'll need to know the impedance levels
you are working with. You need to have a known source resistance, for
a start: since many amplifiers have a very low output resistance, you
should probably add some resistance in series between the amplifier
and the headphones. Then, assuming the headphones themselves are
reasonably resistive and something on the order of 32 ohms (fairly
common, I believe...but yours MAY be different), if you have used,
say, 10 ohms from the amplifier output, that gives you roughly 7.6
ohms, taking them in parallel. Pick the capacitance to give you the
rolloff you want: C = 1/(2*pi*f*7.6ohms) Because the rolloff will be
quite gradual, I'd be inclined to pick a cap that starts the rolloff
just above the CW freq you listen to. I'd personally go for about
1kHz...then C is about 20uF. I'd avoid trying to do that with
electrolytic caps, but you'll end up with some fairly large ceramic or
film caps doing it. (I'd get serious about the whole thing and build
an active filter with MUCH smaller parts...but then comes the chore of
powering it and all.) -- But for a 2kHz rolloff, it's only 10uF, and
if you used a larger series resistor, say 33 ohms, you get down (at
2kHz rolloff) to about 4.7uF, which is not too difficult.

Cheers,
Tom

1598. HB DX-pediton

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-24 20:32:12 UTC
From: n2cqr@clix.pt
Message-ID: <3c794da9.37594208@news.clix.pt>
Source record: 46134

I'm back in the Azores after 10 days in the Dominican Republic. I was able
to get on the air (on 17 meters) with my Homebrew QRP DSB rig.

The transmitter is modeled (very roughly) on the Wee Willy rig. For the RX
it uses three NE-602s (RF AMP, Mixer and first AF) and one LM386. (This RX
arrangement works very well -- this is the nicest DC receiver I've ever
used.) TX has an LM386 as the microphone amp to an NE-602 mixer to three
stages of RF amplification. Oscillator is a VXO that gives about 20 kHz of
coverage.

I powered the rig with 8 D Cell batteries held together with duct tape.
Worked very well and allows the traveler to avoid carrying heavy and
possibly leaky batteries. Headphones were from an old Sony walkman.
Microphone was the size of my thumbnail and came from the an old Sony tape
recorder.

The antenna was a dipole that was strung a bit too close to the ground. And
I found that the < 1watt power out was a bit too QRPish for phone. I think
I will have to get some more drive to the final to bring it up to at least 5
watts or so.

In spite of these shortcomings I was able to make ten contacts: KG2PD,
W2HNV, W5GJ, KA9EES and KE4UYP. DX stations: LA6IIP/P (who I've worked
several times from the Azores), J3/W4QDC, PA1RJ (who reported "beautiful
copy"!) IK1TXM and C6ALC.

I had a lot of fun with this operation. It was kind of cool to do it with
an HB rig.

Hi Guys;
Now this is an Antique Handbook. Its the RCA Tube Handbook, but the year escapes me, there are dates of 1943, 1938 & 46 printed here & there in the book. The leather-ette cover is marked HB-3, Vol. 1-2 but I have no idea if this is Correct because its very old! I do know that it measures 5"w x 7-1/2"h x 2"thick. Seems to cover all aspects of tubes ranging from RCA 00-A detector to 117Z-6-GT/G. Many receiving, Audio amp., etc. There are basing diagrams & much more info.
A great collector book from the RCA co. in NJ.
Here are a few pics, really is in nice shape for its age!>>

> Right... Don't join. When they come to take away your frequencies

This month's Scientific American had an article on using power lines for LAN connections. When I saw that they had broken the 4-20MHz spectrum up into 84 wideband channels it really raised my eyebrows. Sounded like a great opportunity to QRM almost all the HF bands. And are we really going to get on our neighbors case because their computer is keeping us off 40 though 15?

But then I read a little further. They blocked out the ham bands from their frequency plan. Seems they knew the League would be all over them like a cheap suit. Looks like they learned a lesson from the RFID crowd. Not clear who is going to win that one yet, but the League has kept them from wrecking 440 for several years now.

Thanks for interesting information in another poster/thread

...and when I wish to listen to Radio 4 or other stations on LW/MW do
you suggest that I feed the receiver with 75 ohm from the active
antenna? It is no problem with signal strength, Radio 4 on 198kHz is
-50dBm, should work well with less than -70dBm, so the question is
"will 75 ohm upset the selectivity of the receiver?" For this
particular receiver, it is only ECH81 with one tuned RF circuit, the
antenna is coupled via a link on the respective RF-coils, it might
indicate that optimum antenna impedance is non-reactive. Image
rejection is cllaimed to be 80dB on LW and 50 on MW.

I may use this active aerial for shortwave, but suppose other aerials
would be better, it was primarily meant for 136kHz and BC-reception is
just a free addition.

You should be able to fix it using a car regulator. Just pick one that is a module like yours and wire it in. Nothing magic about 12V alternator systems. I doubt John Deere invented their own Alternator or Regulator module.. Likely some mass produced unit.

Jan-martin, I think you have got the point - the artificial antenna had nothing to do with what the receiver input impedance is. Put it on the shelf and forget it.

If you plug in another antenna, (active or not active is not relevant) and the signal strength is good enough and there's no adjacent channel interference then that's fine.

Have a look at the circuit diagram. The antenna is probably tapped into or inductively coupled to a front-end tuned circuit. Rx input impedance will depend very greatly on how the preset trimmer capacitor has been set.

If the Rx was originally tuned-up using the artificial antenna then by connecting a 50/75 ohm antenna the front-end tuned circuit will be detuned a small amount.

So connect your 50-ohm antenna to the receiver and tune up the trimmer capacitor across the input tuned circuit for maximum volume while you are listening to Droitwich.

Then do similar on the mediumwave band with the MW trimmer capacitor. Any improvement ?

It is always best to tune up the front end with the same antenna the receiver is normally used with. It's louder and adjacent channel interference is minimised.

I had this reply when I inquired about the stanard RMA dummy antenna. It seems to me that this is something similar to the artificial antenna pad that you are describing:

Sverre - LA3ZA
-----Original Message-----

From: Crazy George [mailto:munschNO@attglobal.net.SPAM]
Sent: 10. mai 2001 19:59
Subject: Re: standard RMA dummy antenna

Sverre:

Back before everything tried to be standardized to 50 ohms, the manufacturers agreed on the dummy antenna you describe, so that sensitivity measurements could be standardized, and receiver performance directly compared. I think it was supposed to be equivalent to a single wire antenna made of 60 or 100 feet (20 to 33 meters) of wire about 20 feet (6 meters) above the ground.

Crazy George

Sverre Holm wrote in message news:Pine.GSO.4.21.0105101300020.678-100000@granvin.ifi.uio.no...

My Hallicrafters S40A Service Bulletin (about 1950) specifies a standard RMA dummy antenna to be used when aligning the receiver. It says that it "consists of a 200 mmf. condenser in series with a 20 uh r-f choke which is shunted by a 400 mmf condenser in series with a 400 ohms carbon resistor."

What exactly is the reason for using this dummy antenna, and what kind of characteristics does it try to emulate?

Nope, no shunt regulators. The usual is to control the field current via a feedback circuit and let the alternator act as its own current limiter. No active components are really necessary but it's more elegant to use them.

The older automobiles used voltage sensitive relays to control field current.

You can test the alternator with a variable resistor in series with the field coil and see how much the output is as you vary it. The diodes in the three phase rectifier act to prevent discharge of the battery into the alternator although when they get old they may start to leak and slowly drain the battery. The diodes are the parts that most usually fail.

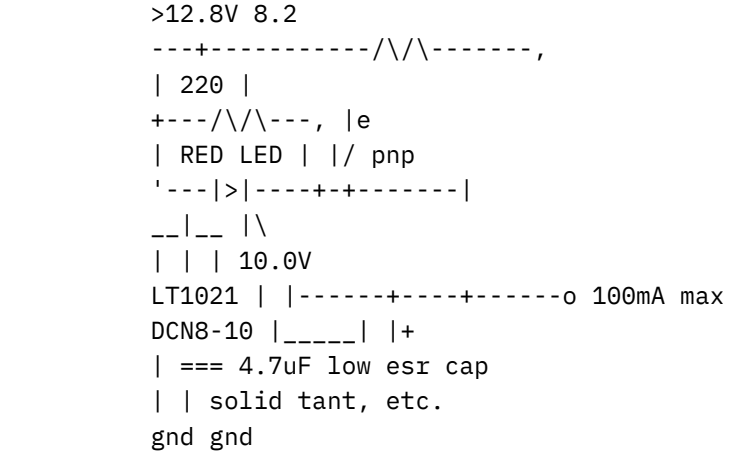
> only game in town for low-noise regulation.

One solution is to use a precision voltage reference IC as the regulator. For example, an LT1021 in the DCN8-10 version costs only $3.17 (singles), yet has 1% initial accuracy and less than 4uV p-p of 0.1 to 10Hz noise, and 2.2uV rms in a 10Hz to 10kHz bandwidth. It also specs 105dB of ripple rejection, so 0.5V of input ripple should create under 2.5uV at the output.



The LED lights up as the circuit current limits. In one variant, a darlington PNP power transistor with a green LED and 0.25 ohms of emitter current-limiting resistance would allow up to 2A out.

Linear Technology points out that to achieve a low 1/f noise level it's necessary to place a plastic-foam insulator around the LT1021 and lead wiring to prevent air-current turbulence with associated thermoelectric voltage changes. They suggest up to 10X more noise without an air shield, and show a graph with 30uV p-p excursions in

a few minutes - were they doing some hand waving? :-)

The noise compares to 86uV for an LM723 in its usual configuration.
However the venerable 723 with an RC filter after the zener stage is
claimed by NSC to achieve 2.5uV rms of noise (100Hz to 10kHz), which
the LT1021 only slightly betters, although without the help of an RC
filter! The LT1021 has less 1/f noise and must do better overall;
it's one of the best-rated parts in AoE's table 6.7, page 336.

Hmm, I wonder, do typical 723 chips ever exhibit popcorn noise?

Thanks, /.-.\

Hi John,

I just Googled and got 61,000 hits on low noise regulators. I checked the majors - Motorola, NatSem, Philips, etc.

It seems they are all on the bandwagon for low noise LDO regulators. Typical specs are 30uV to 40uV up to 100KHz, and 150mA to 250Ma load current. All the ones I checked use a PNP to drive the output, which is what you'd expect for a LDO. Motorola and Philips don't need an output cap.

The biggest problem is they are all low voltage - 1.5V to 5.0V, and there is no access to the divider to change the output. So it looks like the 723 is still the best solution for higher voltages. Fortunately it still seems to be in volume production, at least at NatSem.

Now, about those filters. Here's the shape I'd like to see:

http://www.iscointl.com/aboutoverview.html

It's the red curve:)

Best Regards,

Mike Monett

The 28V operation is a problem for most common ham applications. They can
be used, but they would not be the first choice for many applications.

How do you mean "first timer"? If you haven't built anything, you might want to start even simpler. Start by building simple little bits of test equipment, things that will be useful but are only one stage each. This will give you a chance to do some soldering. You won't have to worry about damaging expensive parts, and for most of these, you can get parts off scrap circuit boards and if you mess something up, just start again without having wasted money.

You'll need some sort of power supply, and they are relatively straightforward to build.

One of the most useful pieces of "test equipment" has always been an audio amplifier. Nothing complicated, just a 386 IC (like you'll find in a lot of receiver designs) in a box with it's own power supply and speaker. Then, whenever you need to check some sort of audio signal, you have an amplifier around to listen to it.

Build up some crystal oscillators. Way back when I started, the first few projects that I tried didn't work (and I never did get them to work) despite copying the parts list from the magazine and going down to the parts store. The first thing that did work, was a really simple crystal oscillator, using a transistor that I took off a scrap circuit board. Have some sort of socket, so you can plug in various crystals. If you happen to have the right frequencies, you can use them for testing a later receiver (ie use it as a really cheap signal generator).

Some sort of audio oscillator is always useful, for testing audio circuitry. I've tended to breadboard something when I've needed this sort of thing, but a few years back I finally built up a genuine "signal injector". The ARRL Handbook has a circuit or two. It's just an audio frequency multivibrator; since it's full of harmonics, you can use it for finding faulty stages in radio frequency circuits.

After that, or instead of that, you might want to build up a receiver putting each stage on a separate piece of circuit board. The audio amplifier here, the mixer there, etc. This again has the advantage that you can have some sort of results after just a bit of effort, and if you mess up a stage, you won't damage the whole thing. Years ago, there was a series of articles in QST along these lines. Build up the audio amplifier, then add a mixer stage, and an oscillator. There, you have a direct conversion receiver. Add a mixer and another oscillator, and you have a simple superheterodyne receiver. Add a filter, and the receiver gets better.

One of the greatest things invented has to be copper-clad circuit board. Yes, you can lay out a pattern and etch it, but it's really useful for breadboarding purposes. It gives you an easy to cut building material, and the copper, which is easy to solder to, gives you a really good ground surface. Whenever something is connected to ground, you solder to the circuit board, and then the rest of the circuitry sits above that. It is really easy to change if you make a mistake, or want to change something, or start all over.

How about putting two LDOs in "series" ?

The lower 5 V regulator would get the full input voltage (say +12V)
and generate +5 V and all output current going into a load resistor.
The upper regulator would be connected between the full 12 V DC input
and the +5V output from the first regulator, thus, voltages up to 10 V
could be generated.

The resistor at the lower +5 V regulator from output to ground must be
capable of sinking the worst case idle current from the upper
regulator, usually a few mA, so a 0.1-1k load resistor should be
sufficient.

Since the noises generated by these regulators have a random phase,
only the noise power is summed, thus, the combined noise voltage is
only 1.41 times the noise voltage for a single unit in a 5+5 V combo.

Rob: Build a little CW transmitter first. Make some QSO's with it.
Do a Web Search for "Michigan Mighty Mite."

Then maybe a direct conversion receiver. But not for 10. Easier to
start out with something on 75 or 40.

Start building a tech library. And a stockpile of parts. And get a
simple multimeter. Arrange a good workspace.

Good luck! Have fun! Start out slow and don't take on anything too
complicated at first. Don't be afraid to ask for help when you get
stuck. We all get stuck from time to time.

Obsolete devices tent to be very expensive but this
does not mean that amateurs are likely to pay $100
for a 30 Watt transistor. There are easier
and less expensive ways of generating 30W.

> But we could use a new hard drive and some software for the house,

Buy a nice new hard drive and go to www.linux.org to see how
you can get lots of very good software for free.

> I've been told my fellow hams are too cheap when it comes to this kind of
> thing, but they're the ones most likely to build things with these, right?

The market will decide how much they are worth. You will
either have to accept the going rate or hold on to them
in the hope that you will get a better offer. I'm a keen
homebrewer and I certainly wouldn't pay 50, 25 or even
10 dollars for them. Sorry! that's probably not what
you wanted to hear.

DDS takes too much current though it is certainly simpler once you have the
board - no need for mixers/filters etc for the L:O
What about spurs - how do these perform in a European situation with lots of
strong local signals on say 7 MHz?

Indeed, an ideal draftsman's curve, 1% flat-top pass bandwidth
with 0dB loss, to 90dB attenuation with 0.2% frequency change.

Sadly "low-noise" only by the force of their own claims, in reality
about 10x higher noise than the 723 (with a reference capacitor) and
other truly low-noise regulators.

The 7805, LM340, and 723 are not LDO regulators. They might be
comparing their performance against the LM2940, which is spec'd at
700uV from 10Hz-100kHz.

It's good to have something real bad to compare yourself against:)

Best Regards,

Mike Monett

> Rowland Institute for Science /// \\\
> Cambridge, MA \/ \/

Win,

Did you see how they measure the noise in the LT1021?

"Note 6: RMS noise is measured with a 2-pole highpass filter at
10Hz and a 2-pole lowpass filter at 1kHz. The resulting output is
full-wave rectified and then integrated for a fixed period, making
the final reading an average as opposed to RMS. Correction factors
are used to convert from average to RMS and correct for the
non-ideal bandpass of the filters."

I wonder if this is a valid method of treating Gaussian noise, and
why they didn't use a conventional true-RMS meter like the HP3400A?

Best Regards,

Mike Monett

Right... there are plenty of specialty parts, but nothing in the 723's
league that I can simply order from Digi-Key or drive down the street
and buy off the rack at Active.

Just as important, there's nothing I can just substitute for a 78xx.
What I really want is a "78LN05" or a "78LN12."

Win's circuit with the LED is pretty nifty. I may try that next time I
find myself reaching for a Zener.

It was published in the RADIO COMMUNICATION HANDBOOK (RSGB). I don't
have the book but I have got a reasonably good photocopy of the circuit.
I can't use my scanner at the moment, I'll see if I can get a good
shot of it with my digital camera.

Also, have a look at Charlos Potma's web-page. See my links page.

> I may even try a discrete solution using DG MOSFETs

I had a pair of mosfets in one of my rigs. They have
plenty of gain and very very low noise. I found it
difficult to get reasonable AGC characteristics with
the circuit I used. MK-II has got a DG FET as the
first IF amp and an MC1350 as the second IF. This
combination works really well.

You might be able to use the same crystals for the BFO/CIO.
It is quite easy to pull a crystal down by a couple
of KHz by putting a little inductance in series with it.
It's not as easy to pull them up in frequency.

> DDS takes too much current though it is certainly simpler once you have the

I don't have one myself so I'm not really qualified to answer. If you
use a high clock frequency, a relatively low LO frequency and a good
LPF of BPF on the DDS output, the spurs should be quite low. If you
want the DDS to directly generate the LO signal for the higher HF
bands, then I would expect fairly high spurs on the LO.

I really must get around to buying some DDS chips. Is the AD9850 still
the best one to start with?

Source record: 46079

Hi,

I am hoping that some of you RF guru's can steer me in the right direction.

I have a small ferrite antenna (ferrite rod, coil and cap) which is tuned to 60khz for the WWVB atomic clock signal. I need for the antenna to stay tuned over a large range of temperatures (-20 to +60 C).

Does anyone know how to do this? I have heard that you can use a varible capacitance diode for this?

Thanks and God Bless you in Chirst!
Stephen

1642. Converter/receiver for 136-138kHz

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-02-25 23:01:02 UTC
From: la8ak.xnd@online.no
Message-ID: <3c7abe79.427854841@news.online.no>
Source record: 46081

planning to build a converter for 136-138kHz, but have not yet decided
if I should use 60 or 100kHz xtal filter for ultimate selectivity
since nearby signals are 50-60dB stronger than amateur signals on
136kHz. See http://sk7do.te.hik.se/~sm5bsz/xtals.htm

I am not looking for a simple design, but need some ideas to start
constructing the converter or receiver, have checked
http://home.swipnet.se/~w-54761/lflinks.htm but it doesn't show
receivers, also have the LF Source Book (G3LDO).
I have some coils (Q=650) of 1.5 and 4.6mH, but they have no tapping,
could make a good bandpassfilter on VLF

Okay, this is not an alternator. It's a magneto.

john deere calls it an alternator and i have to agree...
there aabout 20 poles on the stator..
in addition there's a magneto for ignition.

Henry;

Do you have a shop locally that specializes in alternators and starters ?

They generally have just about anything you would need for that type of alternator.

If the point was to measure "1/f" noise, we expect that to be
negligible above 1kHz anyway.

As a guess, it may be that a conventional RMS voltmeter does not have
a long enough time constant for 1/f work.

The antenna is a coil on a ferrite rod. It is tuned to resonance at 60
kHz by a capacitor or a set of them. Ceramic capacitors are
manufactured with temperature coefficient ranging from negative to
positive values (it depends on the dielectric material). It is common
to neglect this fact for many purposes. You should select the tuning
capacitor(s) with such temperature coefficient to compensate the
temperature coefficient of the antenna. This way, the resonant
frequency of the circuit will remain constant during temperature
variations.

I have a board using the AD9854 on my website
I havent tried the AD9850. It has less DAC resolution (10 vs12 bits for the
9854)
This would translate to worse spur performasnce.However it is somewhat
simpler to drive.
Have not used the DDS as a receiver LO however. Perhaps I will hook it up to
my test receiver with a wire antenna and try it
Alternatively the QRP rig has a sensitive receiver.
It works well as a sweep generator - I could try making up a few of the
filters mentioned on Aleksander Stares page and see how how they perform.

I missed Win's LED circuit, but I suspect I can guess it.

Many years ago I had a need for a low noise reference, with a decent TC but did not need very high accuracy. I did it using a 2.2V zener with a TC of -2mV/deg C which compensated for the associated transistor Vbe drift, resulting in a constant emitter current (and voltage).

The important thing to note is that at low voltages, Zener diodes are really Zener diodes, and have very low noise. At higher knee voltages so-called Zener diodes are actually avalanche diodes, which can be very
noisy. The transition between the two modes of operation is around 5.6V - the TC of the two modes is opposite in sign, you get cancellation
when the two modes have about the same contribution.

I'm not sure whether these low voltage zeners are still readily available,
however.

Keeping the antenna in tune will be the least of your problems. The
remainder of the receiver and equipment will be much harder to keep going
over THAT temperature range. And the DC battery supply will be extremely
unhappy too.

In any case, the candle-fat holding the turns in place on the rod will be
runny at 60C.

Suggestion - don't use a ferrite rod - use a whip with an air-core
tuning coil with a lot of turns on it.

Or use a small loop antenna. It will be just as sensitive as a ferrite rod.
Nothing magic about ferrites.

Ian Buckner wrote:
>
> I missed Win's LED circuit, but I suspect I can guess it.

It wasn't using an LED as a low-voltage reference. Instead the
LED played a current-limiting role in LTC's circuit:

```
>12.8V 8.2
---+-----------/\/\-------,
| 220 |
+---/\/\---, |e
| RED LED | |/ pnp
'---|>|----+-+-------|
__|__ |\
| | | 10.0V
LT1021 | |------+----+------o 100mA max
DCN8-10 |_____| |+
| === 4.7uF low esr cap
| | solid tant, etc.
gnd gnd
```

The LED lights up as the circuit current limits. In one variant,
a darlington PNP power transistor with a green LED and 0.25 ohms
of emitter current-limiting resistance would allow up to 2A out.

The application notes for the demodulator I am using warns that the
ferrite antenna must be temperature compensated. I will do some tests
soon. So, I don't know how much it actually effects it.

Unfortunatly, my application involves these devices being in remote
sensing boxes that actually do see these kind of temperatures.

As for the whip antennas.... how much would they cost in large
quantities? The ferrite rod antennas run about $1.30 each.

Can anyone steer me in the right direction as to a good book on this
topic?

Thanks again and May God richly bless you in Christ

==========

You seem to be starting right at the begining. Before you start buying
anything in quantity you MUST get one complete receiver FULLY PROVED &
WORKING.

If you think a ferrite rod antenna will work after a fashion, first obtain
one and make a start. THEN you can start worrying about temperature
coefficients. It might matter less than you think. But you won't know
until you have a very, very deep freezer plus a thermometer down to -50C,
and a hot oven plus another thermometer.

A whip antenna is just a 3 to 5 feet brass or steel rod or tube, 1/4"
diameter, strong enough to support its own weight, insulated at the botton
end. Like a car broadcast antenna. But you'll also need a simple ground with
a whip. Depends on whereabouts it will be used? Have you already got the

receiver? Will that work with its battery at the exteme temperatures? Otherwise you are just wasting time.

Get a thin book from your local library or book shop on simple receiving antennas. Any radio amateur book about antennas might help. But do not expect to find an antenna ready designed for your purpose. Ask the librarian.

I don't think the people on this newsgroup will be able to give you much more help until you tell us MUCH more about your project. We are floundering about in the dark at present, wondering whether we might make things even worse than they are.

What you ought to be asking yourself -

Does the ferrite rod antenna increase or decrease in frequency as temperature increases ? By how much ? How much does it matter?

What is the field strength of the 60kHz transmitter at the receiving site ?

Is the ferrite rod likely to shatter at the extrememly cold temperature ?

Has the receiver already been designed and its input circuit fixed ? What input signal level does it need ?

Hi Stephen,
The _Amidon Inc._ book has curves of initial permeability vs. temperature for the various types of ferrite they sell. The curves are not linear, although portions
of some of them might be construed as straight enough if you squint at them just
right. This means you may have a difficult time with the temperature compensation.
Do you know the type of ferrite used in your antennas and the physical dimensions?
(The permeability of the rod depends much on its physical dimensions.) You will
probably have to experiment and seek guidance from Jehova - expect to be tested.

May The Lord bless you too.

Hi,

Thanks for reading. Have lots of stuff to sell. Parts, tubes, etc. But the one thing most in the "homebrew" sector is:

I have a few coils, maybe copper (?) of a reasonable size. Look like homebrew transmitter coils or something. Also have a spool of wire. Not sure what type. IF you have any interest in anything, can e-mail pictures. MOST parts are going very cheap. Coils are about $2 - $3.50 each.

Shipping is extra on all items. ALL are sold as is regardless the condition - new or used. See tag for payment details.

Thanks again.

A followup....
I got the fuse lamps that I had ordered and got the radio lit again.
Turns out all the 'fuse lamp clips' had come unsoldered from their PCB
and the bulbs were in fact ok.
At any rate, yes, the lamps are a sealed glass thingie and the tips are
simply soldered on. Methinks you could either build up the flat ends
with solder or maybe even remove the tip ends from your burnt out lamps
and solder them on to the new ones.

>
> I wonder if this is a valid method of treating Gaussian noise, and
> why they didn't use a conventional true-RMS meter like the HP3400A?

Win,

I was curious about the correction factor needed to convert an
average-reading voltmeter to rms when measuring a gaussian signal.

Analog Devices shows two different values in their conversion
tables:
```

Source rms value average %error url

AN268 0.333V 0.266V -20.2% [1]
AD736 0.333V 0.295V -11.496% [2]
AD737 0.333V 0.295V -11.4% [3]

Terry Ritter quotes from the Art of Electronics [4]

"You can use a simple averaging-type ac voltmeter instead . . . ."
"To get the rms voltage of Gaussian noise, multiply the 'rms'
value you read on an averaging ac voltmeter by 1.13 (or add 1dB)."

This corresponds with the information in AD736 and AD737, but it
would be nice to find the derivation.

A derivation is in "Professor Leach's Noise Potpourri" [5], at the
end of Chapter 3 - Characteristics of Noise. [6]

The correction factor is 2 / sqrt(pi) = 1.12837916709551

"Thus the meter reading must be multiplied by 1.128 to obtain the
correct reading with a Gaussian noise voltage."

Rounding 1.128 gives 1.13, which is the value shown in AOE.

Using an average-reading voltmeter instead of a true-rms may give
unpredictable errors. An average-reading voltmeter is usually not
designed to handle a large crest factor, and the correction factors
assume the noise is truly Gaussian. It may not be.

Terry Ritter has done extensive analysis of noise generators, and
shows that a noise generator that is not completely characterized
may have significant errors. [7], [8]

Terry's results show a true-rms measurement may give more repeatable
results than an average-reading with an unknown noise source.

As a side note, Dr. Johnson used a true-rms meter in his July, 1928
Physical Review paper on resistor noise. He used a thermocouple to
measure resistor noise. [9]

Nyquist presented a theoretical analysis in the same issue. [10]

His concept of two resistors separated by a transmission line is
still used to derive Johnson noise. [11]

I can't help on the "how to" but can report that the delay through the tuned circuit will change with tuning (temperature). This means the changing delay will show up as a frequency (phase) difference that may be large enough to affect your measurements.

Another ham and I were talking the other day here at work. We were duscussing our miniature vacuum chamber that we use for vacuum compliance testing.

He mentioned that he wouldn't mind trying to make his own transistors some day. Not the modern stuff, but something equivalent to the 1950s transistors.

I mentioned that it would be easier to make your own vacuum tubes.

My next comment was that you could use burned out light bulbs (finally a use for the things!!) because the hardest part would be the glass to metal seal. Every light bulb has at least two of them. What else you would need would be a small spot welder, a torch for glass working, and a vacuum pump (and associated miscelanea). You would also need a suitable material for the elements. The filament would be easy---old light bulbs again. Envelopes could be made from old glass jars. If you had them permantently connected to the pump when in use you wouldn't even need that great a vacuum tight seal---just keep the pump running.

I remember reading, I think in '200 Meters and Down', about a ham back in the 1920s that made his entire station with homemade tubes. What I was wondering is if anyone is crazy enough now days to be doing this.

One H. P. Friedrichs has been building his own hobbyist tubes and
transistors for some time now. Unfortunately, all the on-line links I
have to his work are broken. I do know, however, that his book "Voice
Of The Crystal", wherein he describes how to actually *build* radios
from scratch rather than just assemble radios from parts, is available
from Lindsay Books: http://www.lindsaybks.com/bks2/vxtal/index.html

Yes, there is someone crazy enough. Unfortunately, I've lost his URL, but he is the author of the book "Voice of the Crystal" which shows how to make crystal sets from materials found at home. He had a go at making his own transistors, but it turned out to be too difficult, so he decided to make his own tubes instead. Last time I looked, he had a few samples. A search for the book title should yield his name, and you can go from there.

Kind of confused by this one (the following). I have received many QSL's
from DX that I did not originate (I did not send them a card first) so what
makes receiving a card from a eQSL log any different than a paper one ??

Come on people eQSL are the way it has to be done going forward into the 21st
Century.

Ron

"eQSL does not do this. eQSL receives a log and immediately makes
cards available to all stations in that log without checking the
information the other station has in his log or on his QSL. This
is not acting as a QSL Manager; this is just plain presumptive
QSLing. It is not adequate that the receiving station look at
the QSL and confirm it. How many do you think will refuse a QSL
from a really rare one who put the wrong call in his log so the
eQSL went to the wrong person, or if the signal reports don't
match, etc? There is no independent check here, thus eQSL is not
performing the duties of a QSL manager, thus the eQSLs are not
accepted by ARRL.

The magnets in an alternator are electromagnets so the output can be
controlled by the field current.

This may well be a matter of difinition, but if what you have has
permanent magnets, then no other kind of alternator regulator will
work there, as they all work on a completely different princilple.

To be fair, I have no idea how a magneto based charging system might
work, unless it just, as someone else suggested, uses a simple shunt
regulator.

How did we get down to -50C? I only saw -20C in the original posting,
which is about what a standard home deepfreeze will do, and less
severe than a N. Dakota winter.

Cheers,
Tom

Do heed some of the advice you've seen here: get things working at
room temperature first, with an eye toward the wide temperature range
(e.g., use parts rated for the range, and understand what will happen
as each drifts according to its temperature coefficient...only a few
of the parts' temperature variations will really matter, and good
engineering judgement will tell you which they are), then see what
actually happens over temperature. If you're confident you have the
receiver (and power source) nailed but are still worried about the
antenna, test it separately. If it looks like it will be a serious
problem, evaluate a bunch of them so you can see statistical variation
from one to the next. Try to get ones made from different batches of
ferrite.

If you're lucky enough, you'll find you don't need any compensation.
If you're a bit less lucky, you'll find you can get by with a simple
open-loop compensation. But maybe you'll decide that the temperature
never changes so rapidly that you can't do the occasional "autocal"
cycle, and that _might_ be the cheapest solution, depending on what
else is already in the system. Yes, there are variable capacitance
diodes, but that may or may not be (part of) the "right" answer for
your application, which you still haven't told us much about. As Reg
suggests, the right answer may be a different kind of antenna. Or
maybe a whole different kind of system: how about using GPS, for
example?

If it were critical to keep the antenna constantly tuned to the right
frequency, I can imagine a system in which you inject a known amount
of 60kHz + delta and 60kHz - delta, and you constantly monitor the
response of the antenna to those frequencies and keep it tuned
accordingly. But my impression is that's way too complicated for what
you are trying to do, no?

Cheers,
Tom

The 200 Meters and Down piece was inspiring. As I recall our intrepid
homebrew hero used pits of broken glass to fashion the envelope.

There was also a QST article (mid 60's I think) about an Argentine
amateur who made his own tubes. Discussion of this subject quickly
degenerated into a flame war on the Boatanchors mailing list. "Can
to! Can Not! etc.)

I remember hearing about guys who were working on homebrew point
contact devices. When you think about it, the galena--cats whisker
detectors were homebrew solid state diodes.

Ah, homebrew active devices! Imagine the bragging rights: Store
bought transistors? Appliance operator!

I seem to remember some articles in a UK publication (Practical
Wireless or Wireless World ?) in the early days of transistors about how to
make your own point contact transistors. It's a wee while ago but from what I
can recall it involved breaking open (carefully) Ge point contact diodes and
combining the piece of Ge with 2 point contact whiskers, think they got
some gain out of it but don't know what the frequency performance was like
- but in those days an Ft of 300 kc/s (well that's what it was in those days !!)
was an HF transistor !

If anyone is thinking about making their own valves/tubes suggest
they get a copy of either Gerald F.J. Tyne (ex-8KN) Saga of the Vacuum
Tube (reprint publ. Antique Electronic Supply, Temple AZ) or V.J. Phillips
Early Radio Wave Detectors (The Science Museum in assoc. with Peter
Peregrinus Ltd., London ISBN: 0 906048 24 9). The early valves/tubes were
very crude, simple devices and should be quite easy to duplicate provided
you're not looking for repeatable characteristics !!

Must go and have a cold shower, I'm beginning to fantasise about
memories of darkened shacks and faint blue glows to be seen inside 813s
mounted on open chassis in 19" racks ....

Sounds impossible to me.

Good, yes, fast, no.

Dan's only takes orders by snail mail so it seem to me it's always a 2 week wait. I've ordered from him maybe a half dozen times, and never been disappointed, but it always takes a while for the pony express.

OTOH, he has good stuff, outstanding prices, and for a lot of what he has, there's nowhere else to get it.

..

I think the diodes that were used were 1N21 (or 1N23), as these were/are point contact diodes.

I think the blue glow was the 816 rectifiers. If the 813 showed blue you had gassy tubes. :-)

Hey gang...I found a great deal on PN2222A's today.

I had to buy the whole lot though to get the price.

I have 9000 to sell.

500 for $20 or 1000 for $35

Now is the time to stock up.

Add $3.50 for shipping in the USA

I will ship to non-USA addresses. Just send me an email and I'll figure out
the shipping for you.

I worried about this too with my TS870 and Drake L4B. I used a power fet (IRF510 available at Radio Shack) to key the relay. I use the +12V available from the radio (on transmit) to drive the fet gate thru a resistive divider that lowers the 12V to 4V which is enough to switch the fet.

As I recall your SB220 has over 100 V on the relay so you might need a higher voltage fet if you try this scheme.

>regulator.

For many years I used a "Windcharger" generator to run my hamshack, and
the only way I could keep that think from overcharging my battery on a
really windy day was via a shunt regulator. I used two big transistors
which "dumped" excess current into a couple of one-ohm 100-watt resistors.
Worked really well.

Unfortunately, after about 15 years, the trees near my tower grew higher
than the tower and pretty-well took the wind out of my sails, so to speak!

Hello,

I wonder if anyone has any pointers to sites, books, source code listings, etc., on the subject of sound card programming. I am thinking of starting a spectrum analyzer project (half software, half hardware based) and wonder if the sound card might be a more convenient port to my PC rather than the usual USB/parallel/serial way in, as well as being a useful DSP resource.

Any help would be appreciated. I have already started a web search but am unlikely to find every nook and cranny. The existence of top grade software like "MMTTY" tell me that the info must be out there somewhere.

Our usual Linux advocate is probably still asleep.

Have a look at some of the open-source DSP software
for Linux and the other NIX's.

My favourite is XAnalyser by Arvin Schnell.

This site will show how to use C++ to use the soundcard to fill a
buffer. From there, you'll need an FFT and a plot routine. I've got
them in C++ if you want.

Jim
To be playing in Office (Excel) you have to use VBA (Visual Basic for Applications). It is the usual conundrum of computeing, it is the same thing as VB but vastly different. If Bill and his magic crew did not concieve of the fact that anyone ever wud ever want to do what you want to it probably can't be done.

VB will let you access the sound card - you say and I believe you - but VBA may not. And VBA is the language that is used to automate, and custom design user applications based on Office applications.

Group: rec.radio.amateur.homebrew Date: Thu, Feb 21, 2002, 10:19am (EST-3) From: jim.bolinger@lintek.aeroflex.com (JLB)
Don't mean to get testy here, but my question was about using ***Visual Basic*** from ***inside Excel***, not C++!!!
Since I said that I have seen how to use the sound card, and how to write Excel macros, it follows that I **have** done a web search. And I have seen the site in the link.

OK don't get testy. Unless you are using a version of Excel prior to 4.0 "macros" do not exist. Your "Macro Recorder" builds a script in "VBA". I have written a multi-sheet Excell based application that captures keystoke information, and builds a mainframe upload file, that interfaces w/ legacy equipment, the programing of which originally expected input on 80 column punch cards' Did not use a line of Visual Basic. Could not. Many lines of Visual Basic for Applocations later the program worked as desired. If you want to be in Excel when your sound card is talking to you, you are going to have to use VBA. Don't let how similar they look fool you, they are not the same. You may or may not be able to make the calls you want.

This could be the start of a FAQ as far as uk.r.a is concerned; after
all this sort of Q is asked fairly regularly. A "G5RV" section might
also help to dispose of the myths surrounding this amtenna.....

1729. Re: 10.7 Mhz IF and HF

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-01 22:53:10 UTC
From: Pete Gianakopoulos <n.gianakopoulos@worldnet.att.net>
Message-ID: <qDTf8.7382$gK2.533131@bgtnsc04-news.ops.worldnet.att.net>
Source record: 45971

I've been using a 10.7MHz 1st I.F. for some of my receivers, and as long as I use a doubly-balanced diode mixer, the spur at 10.7MHz is right around .25uV. When an antenna is connected to the receiver, the spur is masked in the antenna noise.
Now, what Mr. Black did say was correct, especially with some of the older mixer designs. If this approach was attempted with some of the older topologies, there would be a very high level spur at the I.F. That is one big reason that the Hallicrafters SX122, and some of their other receivers with that 1650KHz 1st I.F. omitted that range just above the MW band. The Drake '4 series was another example of this omission, except in this case, it was in the 5.465KHz range.
If you run a spur simulation, you do see the benefits from using a higher I.F.; much fewer inband spurs. For anybody interested in seeing what I've done with a successful implementation of a 10.7MHz 1st I.F., feel free to contact me.

> smooth ?
==========
Do you mean the insulated wire used for EHV in Monitors and TV sets?
It is single strand wire (tinned copper) with 2 different layers of
insulation , the outer one being smooth.
I have also a short length with multi-strand wire , both type suitable for
up to 1 Ampere
I found a length of a couple of metres at a flea market for use in a valve
linear amplifier, but the 2 x 50ft length you require will probably only be
available from a specialist wire/cable supplier .
If you know a monitor /TV set production or repair facility ,perhaps you can
get the required info from this type of source.

Good luck

Frank gm0csz.kn6wh@ntlworld.com

Hi Geoff.
Yes Birkitts of Lincoln are still in Business,i call in there
every couple of Months,John the Founder is still
in the Shop most Days and also attends quite a few of the Rally's,a real
Radio Shop i call Birkitts,oh nearly forgot
re the Web page for Birkitts no they dont have a Web Page.
Cheers,
Terry.

Source record: 45973

Hello,

My station clock that I built from a kit in 1975? has the National MM5314 chip in it. I have an extra chip and am thinking about a new clock.

Does anyone here have a data sheet?

Of course, I'd pay reasonable copy/shipping charges.

Clyde

Source record: 45974

Hello all,

I have been looking for information on Super Regenerative receivers and have had no luck. All I seem to find is semi-complete cookbook examples nothing really comprehensive (mostly tube stuff). I am looking for a solid state Colpiits based J-FET or BJT design, it would be great if data and an explanation of what is going on in the circuit would accompany the schematic. I am looking for somthing in the VHF/UHF band, preferrably UHF but VHF is just as good for starters. I would appreciate any help you can give me, please send responses to rfmac2000@yahoo.com

Thanks!!!

Best Regards,
Nick

Hi Clyde,

Utterly wierd. I just looked up that data sheet two evenings ago,
after not having opened that book for probably five years (having
nothing to do with our recent email exchange, either!). Yes, I have
one. I can probably scan it and turn it into a .gif for you, if that
would work.

Cheers,
Tom

Jim: I guess it is in the eye of the beholder, but I don't think you
can really say that a Heathkit is homebrew. I've run many Heaths and
many HB rigs. When I run Heath, I say, "rig here is a Heath XXX."
When running the homebrew (from scratch) stuff, I say "Rig here is
homebrew." There is a big difference.

Of course, definitions for contests, awards and all that are
established by the organizers.

>with that 1650KHz 1st I.F. omitted that range just above the MW band. The
>Drake '4 series was another example of this omission, except in this case,
>it was in the 5.465KHz range.

well, not quite. Drake 2-A .... 2-C have 455kHz and 50kHz IF for 80m
reception, and uses 80M as first IF for other bands. I have never
experienced spurs on 80m with any of my 2-B's. Using a 4645kHz xtal
filter (as for R-4) you do not need 455kHz in the chain to convert to
50kHz.

I don't see mentioned which coverage is intended, so I will still say
455kHz is an optimum IF - at least for frequencies below 4MHz, and the
solution used is usually sought considering the available sources of
components. In our case - having douzens of SSB/FM/CW/AM xtal filters
around for 5.2, 9 and 10.7MHz we might choose different, but still
application of 4.433, 4, 8 or 3.579MHz xtals in ladder type filters
might be interesting to try in some applications

At the moment I am experimenting with 60kHz xtal filter for 136kHz RX

What *I'm* looking for is an amp for 6 meters, like one of those little blue Henrys that were around a few years ago. The few 6m amps they sell now have much more power than what I need, and they're not cheap... is there a way to switch the filters on an outlaw CB linear to convert it to 6m, thereby bringing its crime spree to an end?

A "Home brew" is any piece of gear which must have some level of assembly in order to operate. i.e. soldering, bolting together, wiring(internally).
If you must install and or solder in a primary part in oder for the unit to function, it can be called a "Home brew".
This does NOT include taking it out of a shipping box, plugging it into a power source and turning it on.

It is very possible. I have seen this brought up before but it may depend on the design of the amp. Legality brings up a whole other issue that I am sure a few people would be able to pound into your head, but then again it may not matter to licensed amateurs. Anyways, I have a "6 meter" linear amplifier made by a company called Fist Commercial Communications. It has two 6LQ6 sweep tubes in it and when I got it there was a coil tap inside that was obviously moved. I asked someone about it and they said that it may have been converted to 11/10m. So if it was possible to convert this amp, it may be possible with a few other tube/SS amplifiers.

Good Luck!

baxter_family@bigpond.com says...

> Is a kit built transceiver a homwbrew rig?

Not to my perception.

> Is there an official statement of what is and was is not homebrew?

I don't know how 'official' it is, but... My understanding is that
"homebrew" describes some piece of equipment that you, as the homebrewer,
designed and built from the ground up. This is what I was taught when I
first got my license back in 1977.

With that said: We do see the occasional confuzzled person in this
group who doesn't see the 'rec.radio.amateur' part of the newsgroup name,
focuses on 'homebrew,' and makes some post about creating good beer.
Silly people... ;-)

>Is a kit built transceiver a homwbrew rig?

I've seen various "definitions" of "homebrew" for at least 30 years!

PERSONALLY, I don't think ASSEMBLING a kit goes far enough to be called "homebrewing"; to me there must be some element of creativity and/or experimentation (for example, taking one circuit from this magazine and one from another source, then putting them together and making them work, whether by using smarts or just trial and error) If there is no element of chance and no possibility of failure (BEYOND just cold-solder joints), then I just don't call it "homebrew".

On the other hand, I've heard people talk about "homebrewing" an EME station by connecting the appropriate transmitter, receiver, low-noise amplifier, dish, etc., with pieces of already-terminated coax. Since **I** don't (currently) know how to do that, I might call it "homebrewing". But if I ever did that, it would become "assembling" again.

Of course, unless one actually MAKES (not just purchases) the individual parts (tubes, transistors, capacitors, resistors, etc.), then even my definition becomes little more than "assembling"! Even then, an expert physicist might just call a homebrewed capacitor an "assembly of tinfoil and waxed paper"! So I think it's a matter of degree.

I have ASSEMBLED several kits (in fact, I currently have a TenTec Xverter kit waiting to be assembled), I've HOMEBREWED (my definition) several transmitters and at least one receiver "from scratch" (where I define "scratch" as meaning I got the circuit from a magazine and all the parts from my junque box), I've DESIGNED several computers and small electronic circuits (but I still bought--or scrounged--the transistors, IC's, wire, etc., and "just" connected everything appropriately.

I've never made a tube or transistor, but I have "made" a diode, if one counts touching a pointy wire to a piece of Galena "making"!-)

Hi

I have searched the web sites of quite some manufacturers of SMD resistors but could not find detailled information about the parasitics of resistors.

In an application note I found that with a 0603 1k resistor there is a 1.7 nH inductor in series with the resistor.

Can someone here provide more information?

Peter

1761. Transferring Text/Graphics to Front-panel

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-02 19:54:29 UTC
From: Klaus Vestergaard Kragelund <KlausKVIK@hotmail.com>
Message-ID: <3c80d966$0$39855$edfadb0f@dspool01.news.tele.dk>
Source record: 45986

I would like if someone has input to this.

My process of creating "proffesional" looking front-panels is this:

1. Print-out the image inverted/mirrored onto a transparent foil
2. Cover places that need to be transparent with tape.
3. Spray-paint the foil to get the background colour (several times). Better yet use one layer laser-colour foil
4. Cut-out holes for pots and connectors
5. Spray an adhesive onto the foil (or use double-sided adhesive foil as an extra layer) to clue it to the front

I'm using thin aluminium for the front plate by the way

My problem is that I would like two special cases to be possible

1. To have the places where e.g. LCD displays appear clear and the rest of the panel dimm/dull/dead

Solution: Sandblast the foil with the clear areas taped? (stupid idea I guess)

2. Have LEDs light up text that normally is invisible

Solution: Put an exstra foil-layer with the LED text in black onto the background and try to light up the text so it creates a shadow or lights up all the way through to the front?

Any ideas?

Thanks

Klaus

Very low-power un-licensed FM transmitters are legal.

Radio Shack (and others) sell them. I have one.

I'm not sure whether they must be type-approved or not.

1770. 8 Pin SMT Programming Adapter

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-02 20:57:39 UTC
From: k1el@aol.com
Message-ID: <20020302155739.11523.00001905@mb-dh.aol.com>
Source record: 45910

I have a new SMT programming adapter for sale. It is for 8 pin
SOIC 208 mil packages. The following PIC parts will fit in this adapter:

12C508, 12C509, 12C671, 12C672, 18F010, 18F020.

You can obtain more info about it at:
www.logicalsys.com
Do a search for PA8SO1-2006-3

I paid $70.00 for it, I'll sell it for $50.00 shipped priority mail (conus).

Thanks, Steve

Subject: RE: Professionally Printed and
mailed eQSL's
Hi Rich:

Something does not sound right here. You are
saying that Dave is physically mailing out QSL
cards by the US postal system? This is news to
me.

If you are my QSL manager and I send you my
logs by e-mail, I am sending them direct from
point A to point B. Just as if I was sending them
to you by regular mail. This is OK. I remember
somewhere several years ago that some people
used to get their logs over the air on RTTY and
another digital mode (AMTOR I think). Not a
problem.

However, if as the result of a log being sent to
E-QSL, someone goes in and receives a card
electronically and uses it for DXCC, that
e-QSL cannot be accepted for DXCC credit
under rule 2. I spent a bit of time with a simple
shareware program to prove the unreliability of
that method.

However, if Dave, acting as QSL manager
with station logs completes a card (even
one from his printer) and sends it by mail to
you, this is an acceptable exchange and we
have see this often for several years now.
(assuming he phyiscally checks the log). Many
people use self-made cards from their printer.
Each one is evaluated on a case by case basis,
and many times under Section IV rule 4(b) we
have conducted an audit to insure the vaildity of
a card like this.

In cases like this it would be REAL nice if they
used a stamp or placed their initials or signature
on it, but this is not required by the rules.
However, this issue has been discussed and has
been given some consideration.

To clarify, if Dave is sending out cards
through the US Postal System as the result
of the log(s) he receives, this is OK. (This
would basically be operating as QSL
manager).

Regards,

Bill Moore NC1L
DXCC Manager

There was a QST article a few years ago on how to modify a AA battery holder to accept 9V batteries. It involved cutting parts of the plastic out and rewiring the inside of the unit. Has anyone here done anything like this?

I have an old FBA-15 AA battery holder for my Yaesu FT-50R that I replaced. (It had some bad contacts, and while I could revive it by placing aluminum foil in the appropriate places or scrubbing the metal contacts with sandpaper, I wanted something more reliable.)

I still have the FBA-15. What tools do I need to rip out the plastic and metal "walls" inside so the holder will accomodate a 9V battery? How would I secure this 9V battery inside the holder?

Many of those chips became obsolete not long after they hit the markets, or
so it seemed.
I built one clock from a kit, and had to get the clock chip replaced right
away.
If I had to replace that chip now, I'd be SOL, as it stopped being readily
available shortly after I built the clock.
It did work for years, but I wound up leaving it behind when I moved to CA,
and don't know if my brother tossed it or what. he's kinda dumb on that
stuff.
But now, it's hardly worth the effort, unless one wanted to build an alarm
or some such.
And most interfaced to LED's which are a bit hard to get now.
I'd do an LCD version if I did one at all. Though a fluorescent display
might be nice.

1777. TUNE YOUR AMP/RADIO WITH EASE.....

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-02 22:47:29 UTC
From: NI4L <ni4l@charter.net>
Message-ID: <3C815681.85341C4D@charter.net>
Source record: 45917

SSB PULSER....
Works with all amps and Tube
type radios....Tune your gear up without fear anymore.
Easy to install in any mic
or radio.. Uses 9 volt power source.Hooks to audio hot and ground.
Tune your gear to full
output using this SSB pulser. Small enough to fit in the base of a
microphone.
This is NOT A CW PULSER
which key's and unkey's in the CW mode . This works in SSB MODE.
Key your mic push the
moumentary switch to activate the pulser and Tune Away.
Let me give you an
example.....
Tuning a Dentron Clipperton
L amp. with a Icom 751 A radio, Pulser installed in a Ten_tec 705 mic.
set radio to full output on
desired frequency SSB MODE into a resonate antenna of course.....or
dummy load
Set amp to proper band
settings
Key mic and push Pulser
button..... watch watt meter it will show aprox 100 to 200 watts out
when tuned to peak output
using Pulser....Remember don't key too long 10-15 seconds
Then check output using
voice.... It will be full Output 1200 watts
See How easy that was....
The amp loved it and now your ready to talk at Full output.
The same tuning is used to
tune a tube type rig also.
35.00 +2.00 shipping

==========

Some time ago a kind fellow Ham, also on this NG ,sent me an article from
QST
March 1967, by Gerald D. Jones , K2AYM
pages 11- 15 : Six-Meter Kilowatt with 4-400s or 4-125As . Anode voltage =
2000 V.
In addition to the 2 RF power valves ,a screen voltage regulator employing a
6BF5 tube is used ,but of course this can be another type.
Kilowatt is meant as 1000W input as was customary in those days. So the
output is probably 600W max.
The design can be scaled down for lower power .

There is another design for an 80W RF 6m amp by G4IDE , utilising a double
tetrode QQY06-40A or its US (near)equivalent, of which I have a scanned
image on
my system . If you need it pse let me know , if possibe in the next 2 days.

1781. Need help with conventional XTAL FILTER (60kHz)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-03 00:09:20 UTC
From: la8ak.xnd@online.no
Message-ID: <3c81654a.99745091@news.online.no>
Source record: 45921

Tried to copy the SM5BSZ Narrow Filter with 2 * 100 kHz Calibrator
X-tals http://ham.te.hik.se/homepage/sm5bsz/xtals.htm
but cannot vary the bandwidth

Uses a 59.995kHz xtal and feed the filter with a tuned circuit loaded
at the link to xtal with 1000ohm, measured the xtal to be 33pF holder
capacity, and use a 40pF trimmer capacitor which seem to work as it
should, but I am not certain which frequency it should be adjusted at.
If I choose 70kHz the stop-band leakage may still be improved on
75kHz, and opposite
The input coil has low Q (40) and wound on a ferrite toroid core with
1300pF and checked the tuning with Q-meter.

But output load only seems to vary the bandwidth by small degree, more
than 100Hz -3dB bandwidth is hardly possible. Tried different values
of load resistance between 22k and 1M. Tried with and without tuned
circuit at the output, and the tuned circuit consists of 4.3-5mH coil
with Q=650, capacitance = 1500pF. The only measured effect was that
center frequency changed some tens of hertz

Tried to add series resistors (up to 1000 ohm) to the xtal, but it had
little effect.

What I need is 200Hz -3dB bandwidth for my 136kHz converter and 60kHz
IF was chosen since I have many xtals around this frequency

I use a Siemens Level Measuring equipment with 10Hz frequency solution
and receiver follows transmitter, 20 or 2000Hz selectivity.

Paul Cooper <plcooper@starband.net> wrote:

>WTB 2 lengths of 30KV Hi Voltage wire with surface smooth (nylon). One
>length in red and one in black. Both lengths to be around 50 feet.

If you are wanting to run a pair of high voltage wires you can use
RG-8 coax as long as it has the SOLID (NOT foam) dielectric. If you're
running one ground and one HV you just need one length of cable. If
one is + HV and the other is - HV, then use 2 lengths of RG-8.

In most installations, the shield is a welcome addition to safety,
convenience, and voltage standoff.

Actually, You are not SOL...

My station clock seemed to move on to Si heaven after a bad electrical storm....
So I had to buy a new chip. Found it at Debco Electronics, so, they are
available.

I am working on a (sorry guys, please don't gag) a Nixie clock. After I posted
the data sheet request, I realized this wasn't a BCD clock. I still would like
the data sheet for reference.

Charles Kitchin has gone back, looked at the superregen from it's
beginnings eighty years ago, and tried to add to the field. He's had
a number of QST and QEX articles. I've posted about him before,
and I have posted the dates of specific articles. The 2001 ARRL Handbook
has one of his superregen receivers, and probably other recent editions
have the article too.

A few weeks back, someone posted here about how he'd found an article on
the ARRL website, http://www.arrl.org and how he found it too complicated
and that he'd taken out lots of parts. He fell into the trap of the
superregen, ie that it's not really useful, so you might as well make it
as simple as possible. Charles Kitchin has tried to improve the operation,
by adding some parts. It isn't like the depression, when adding an extra
stage would have significantly added to the cost. I found the article
there by doing a search at the ARRL site on superregen.

I recently learned that you can see US patents on the web, at:
http://www.uspto.gov/patft
So you can look up Howard Armstrong's original patent for the superregen,
issued in July of 1922, by visiting that site and looking up
patent number 1,424,065.

I do understand your thinking, Mr Noeding, but I was just using the Drake '4 line as an example. I remember one of the old Allied catalogs talking about the tuning range of the R4 receivers, stating that the unit would cover from 160 to 10 Meters, "save for the range from 5.5 to 6.0Mhz". Anyway, the whole point of this is that manufacturers would generally avoid the I.F. range on their receivers, except for some exceptions as the Collins units that had the variable, and some others. Interesting about the Drake '2 series; I didn't realize that they used a variable I.F. tuning scheme. I've had a few of those units over the years, wondering what the I.F. lineup was, in order to get the triple-conversion tuning scheme. Those were good receivers! Thanks for your input!

I'm doing some research and need an ARRL Handbook from 1991 or 1990.

If you have one sitting on your shelf, make me a deal, (and of course I'll cover shipping on top of that).

If you have both years, make me a deal on both.

Drop me an email at newhall@vt.edu

This is your chance to make room for the 2002 edition!

Source record: 45933

NEWLY AVAILABLE Program "ADDALOAD.exe"
==========

A random length antenna wire may be made resonant at a particular frequency by inserting either a coil or capacitor at any position along its length. For overall wire length, wire diameter and location of the loading component, the program computes either C picofarads or L microhenrys depending on sign of the required loading reactance.

Greatest wire length accepted is 1 wavelength at the resonant frequency. Results apply either to a vertical antenna wire or to both halves of a centre-fed dipole.

The program has an educational facilty to slide the loading component along the wire while observing how it changes value and type.

Download from website below program ADDALOAD in a few seconds and run immediately.

Mini-Circuits has some surface mount mixers, that have a small form factor; these are the RMS series and the ADE series. A good I.F. subsystem is the Phillips TDA1572; this device does come in a surface mount version. If you wanted to go with a bilateral I.F. subsystem, this would not be the device of choice, but if you were to have a seperate Rx I.F. strip, it should do fine. I've been using it after the 2nd conversion, with good results. Those other devices that Eamon mentioned are also very good.

Hi Guys;
After going thru all my boxes-O-Stuff, I came across these 4 E.F. Johnson items that need TLC but are quite reparable!
I have no time or workspace to work on them.
1- Johnson 229-0203-001 Roller, 25uh, Used, Nice but needs from Bearing repair!
2- Johnson 229-0201-001, 10uh roller, Looks unused but has a light crack on one corner of the ceramic insulation, acroos the Long Bolt hole, Can be left as is, seems still strong!
3-Johnson 154-32 Used Air Variable, 30-300pf? Not sure. Used, needs 1 end ceramic end replaced with a Plexiglass copy, A few saw cuts, some filing & 4 holes, easy!
4- Johnson 132-502(#15-147) Dual Section Air Variable, Unused, 150 pf Ea. @ 3500v. Both ceramic ends need to be copied & replaced. But that hard to copy in Plexiglass, needs some patience & time, Very Costly if no repair was required :-)
Here is a Picture>>

I would probably use the 9851, if low current drain is desired. The 9852 is cleaner, but much higher current. I have used the 9851 for a couple of years, and it isn't too bad, but still, it is not as clean as a PLL design. Many in-band artifacts.

>andrew.holmes1@btinternet.com

RS are not welcoming orders from private individuals any more. The Electrovalue retail operation closed about two years ago. I checked this with RS a few weeks ago, and their policy is now "business to business". In other words they have gone back to their old "Trade only" policy.

You can use the RS web site for private credit-card orders, but even that facility is primarily intended for use by account customers when they can't get a formal order number. It's the online equivalent of sneaking in to the RS Trade Counter with a "cash order".

In contrast, Farnell are very happy to accept individual credit-card orders, will take your order by phone, charge essentially the same prices as RS, and have free delivery on orders over ï¿½10.

Further details are on the 'In Practice' list of UK component and tool suppliers, at http://www.ifwtech.com/g3sek/in-prac/components.htm

I try to keep the list up-to-date and useful, so all suggestions and recommendations are very welcome.

You definitely need to find the QEX
article of a year or two back. The
author investigated improving the
superregen's notorious poor selectivity
by controlling the waveform of the
quench voltage.
I note also that Radio Electronics for
Oct 1969 (i don't have it) had a short
paragraph on a 2-FET multivibrator
circuit superregen operating on about
10-20 meters.

HI Folks, Mainline (UK electronic bits supplier) has some SMA2000 ring mixers, they look like Mini-Circuits SBL-1 style encapsulation. Anyone got spec on these beasties?.
They also have SL560C at 7 for 5 ukp, and S-AV7 and M57729H RF PA bricks SAV's are 2 for 30 quid, M57729H's are 28 quid each.
I'll be pleased to order and forward should anyone EX-UK wish to buy some.

Thanks for the info Pete. I'm planning to build a new rig for
2M. I was thinking of using a PLL with the VCO output mixed with
a crystal oscillator and locked to VFO running at 4 to 6MHz to
cover 144 to 146 MHz. A DDS might be a good way of generating the
4 to 6 MHz signal.

Well, the data sheet covers four parts, some of which do have BCD
output. There are also some other MM53xx clock chips that have BCD
outputs. Guess you'll have to latch those and drive 7441's or equiv.
for your Nixies. -- Will you be wanting one of the BCD-output chips?

Cheers,
Tom

I knew a fellow who'd retired from Bell Aerospace over in Buffalo years back and we spent an afternoon talking about those things. He'd worked on both the rocket pack, which had a 60 second endurance, and the jet pack which had a half hour endurance.

He said the rocket pack was really a pretty simple design. It was a hydrogen peroxide rocket, using pretty pure hydrogen peroxide as the single fuel, and a simple silver grid catalyst in the engine neck to 'fire' it. I think the pressurization was with some compressed air to pump the fuel.
The tank and nozzle were mounted to an articulated frame that strapped on the user, and would allow you to swing the nozzle around using a pair of handles. There was a twist grip I think to control the rate of feed of the fuel to the catalyst and nozzle. The fuel was sufficient for about 60 seconds, and there was a beeper that sounded under the helment when there was 10 seconds of fuel remaining.

According to him, they recruited the people to fly it from the nearby University of Buffalo, mostly athletic folks like football players. There wasn't a lot of training other than trying to hover low and do short hops, and he said the only injury in the program was when one of the pilots at a demonstration was waving to the crowd from a raised platform from which he was supposed to take off and fly, and he wasn't paying attention and stepped backwards off the platform while waving.

The original impetus for the design was for troops doing a landing ala the beaches of Normandy. Instead of having to slog their way up the beach

through a hail of bullets, the hope was they could all fly the last 100 yards or so, and leap over entrenched positions.

There was a version that had a small turbine that ran on JP4 or maybe avgas, and it had a 30 minute endurance but he said it was so noisy it was unbearable to be around.

Where did you see one fly? I know they used to do them at football games and such, flying the length of the field. I remember seeing films of that, and of someone flying over a 10 story building. He said that was a bit tricky as you had to have enough fuel left to stop coming back down and it was easy to miscalculate.

Hope that fed your interest.

For Sale:

Lots of parts, tubes, grab bags, oddball stuff. New parts, good circuit pulls, over stocks, some parts maybe no longer found elsewhere. Looking to clear it all out. IF looking for something to start or finish your homebrew project, give me a yell. I may have it. Even have some electrical stuff. MOST is going dirt cheap!

Also, have a couple cases and cabinets from older equipment, maybe good for your projects. These are going cheap also.

If I don't have it today, I may have it tomorrow. Keep my ad handy just in case. OR pass it along to your friends.

See below for terms of sales.

I suggest you consider the RH-40 from Red Hot Radio
(http://www.redhotradio.com). The web site hasn't been updated since
they temporarily stopped production, however, but you can probably find
out via email. I have the 20 meter version and the receiver portion
outperforms my TS-570. The built-in keyer and frequency annunciator
are nice features. If you are interested in a multiband rig, the
Elecraft K-1 and K-2 are very good choices (http://www.elecraft.com).

1820. Electrolytic Capacitor Polarity Identification

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-04 22:57:25 UTC
From: "Jim Hill, w6ivw" <XXslimjimis@cox.net>
Message-ID: <bau78uk37o8l1krcufh5vjabc274kdi13h@4ax.com>
Source record: 45862

I just purchased some axial Xicon electrolytics from Mouser, and there are no obvious polarity markings. The case is indented at one end, and there is a stylized band that could be considered an arrow going from the indented end to the other end.

No information is given on Xicon's web site, but noticed the radial electrolytics have one lead shorter than the other.

How is polarity identified?

Thanks, Jim

1821. TRANSMITTER POWER SUPPLY PROBLEMS

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-04 22:59:46 UTC
From: djnicad@hotmail.com
Message-ID: <ec5747bc.0203041459.3712a392@posting.google.com>
Source record: 45863

Ive got some problems with a power supply that I built from the
following page:

http://www.aaroncake.net/circuits/supply.htm

I'm building a transmitter that needs about 4 to 4.5 amps to be
supplied from the supply to power the different components
correctly, so I thought that this would be o.k to power everything.
When I had built it, to test it out I set the voltage on the
supply to 12Volts and connected a 20Watt/12v (1.66 Amps) light bulb
across the supply terminals to see if it worked... no problem, it
powered the bulb nicely.
The problems started when I connected (in parallel) another 20Watt
lamp across the terminals (40Watts in total/3.33Amps). Both lights
go very dim for a second (slow start up protection?), they then
reach full brightness (12v) for about 3 seconds, after this the
bulbs rapidly dim till they reach a low level.
I know that the LM338K features current limiting as protection for
the I.C, which is what I believe is happening when I connect the
second bulb. What I can't work out is why this is happening when Im
only connecting a load which is roughly 2/3rds of the rated output
current of the I.C (5amps).
I built the supply using all the specified components in the parts
list, I mounted the I.C to a large (oversize) heatsink with a mica
washer and used a 12v fan to blow onto the sink to keep it really
cool. I used a torodial transformer rated at 225VA (oversize) to
provide the A.C.
Ive tried changing the bridge rectifier, just incase the original
was faulty but it hasn't changed anything. Do you guys think I
have a faulty LM338K regulator?
Can anyone also tell me if the components specified in the supply
schematics are right? (to produce the full 5 amps).
Any help would be greatly appreciated.

Thanxs

Well, I have a 5314 that drives 7 segment, and have considered making a CPLD or PAL that goes
backwards from 7 segment to BCD.... I likely wont use the chip in the new clock. Still desire
the data sheet.

But in 2 hours yesterday I did the entire BCD clock design for a CPLD..... It has features that
I really like that I implemented years ago in a microprocessor system in that:

you my change the hours without affecting the seconds,
you can advance the time or make it go backwards easily during setting, hours
independently of minutes.

As for the nixie chat group, Hans, is this a yahoo chat or a usenet News group? If it is a usenet group, what is the proper name for the group?

Hans, thanks for the links....

check out the ansoft web site. You can down a student version of their simulators, which should do nicely for filter simulation.

There should be a large arrow running vertically top to bottom on one side.
Look inside that arrow and see if you can't make out the (-) sign. The
arrow points to the negative lead. Don't trust short-long leads as somebody
could have clipped one somewhere along the way.

Source record: 45870

Howdy......Looks like a neat little power supply you've built there. I believe you are seeing 2 seperate problems that manifest in the same manner (and I'll offer a couple of suggestions to improve this). I wasn't familiar with the LM338K but studied the datasheet for it and noted that (like many regulators) the 5A maximum rating is available only when the difference between the input voltage and the output voltage is 10 volts or less (preferable)....(Pd of 50W = 10V x 5A therefore if you have a differential of say 17V then you'd only have a current capability of 2.94A = 50W). It's important (and often neglected) to keep the input (unregulated) voltage as low as possible and still satisfy the minimum differential voltage required for regulation (LM338K shows 1.25 volts....therefore for 12.0 output you'd only require 13.25 volts input....anything higher just increases the heat dissipated by the regulator). I "suspect" that your input voltage is likely nearer to 35 volts, especially in light of the heavy transformer you used (you might let us know). IF this is the case then your power supply will have a corresponding lower current capability, depending on what you've dialed up for output voltage (lower output voltage = lower current capability due to increased Pd of the regulator).....make any sense?

The second problem I see happening during your 2 x 20W lightbulb load test is this......(assuming you used incandescent lights here): Bulb filaments are lower resistance when cold and therefore draw more current when initially turned on (measure this especially with an analogue meter and you'll see what I mean). Bulbs are pretty nominally rated so your actual current, even hot might be somewhat different by the way (your math is good though!).

So....what I see happening during your tests is this (if my guestimation of your input voltage is ballpark close): During your 1 bulb test you didn't exceed either the maximum current OR the maximum Pd of the regulator and it worked ok.........During the 2 bulb test, initially you may have exceeded the maximum current of the regulator while the bulbs were lighting (caused a momentary cutback) and THEN as the bulbs drew a steady current, likely exceeded the Pd of your regulator (causing it to cutback as the temperature climbed inside the regulator).

What I'd suggest (and have had to do) is to: 1. Insert a 2 ohm 100 watt resistor between your bridge rectifier and your regulator (this will cause a 10 volt drop in the unregulated side @ 5 amps hopefully still keeping your input above 13.3 if you desire 12.0 out....or calculate as required). 2. Lower your input voltage by other means....if you have any line voltage adjustment taps on the primary side, set the tap to the highest voltage position OR change to a lower

output transformer (15 to 18 vac maybe @ rated current). 3. Install an additional NPN pass transistor (or 2) between your bridge output and your load terminals and drive its base with your existing regulator's output....heatsink the pass transistor(s) accordingly.....this solution will work well with your circuit as you have the capability to adjust the voltage to compensate for the additional junction.

Hope this helps.

Nice reply, Kevin.

It was a long time ago, 35+ years easy. As I recall, my old man, who worked at Langley outside Wash.,D.C., took my brother and I with him over to the Naval Surface Warfare bldg over in suburban MD. and it was over there that we "happened" to see a Demo in a parking lot with really not much of anyone around. I have no idea why we were there in the first place.

My pop claims not to remember it. However he did admit 30 years after he left the Agency that he did go through full training down at Camp Perry. Apparently, he also may have put those skills to work when I was still very young. Frankly, things are blurry and he doesn't always confirm what I remember growing up, or sometimes comes up with something totally different. If you aren't familiar with those place names the internet may provide more.

Regardless, I really liked the history you through in there. I had no idea "college kids" ever flew these things. I thought it was all military and test pilots. I'm not a pilot, but as I recall , and based on what you said Jet-Paks could do, you really shouldn't need a pilot's license. Maybe just a License to Kill (Hi, Hi.) Did you and your friend ever talk about building one ?

1831. Re: QRP Transceiver Recommendation

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-05 00:42:18 UTC
From: xpyttl <xpyttl_nospam@earthling.net>
Message-ID: <u8853nm00cvg6b@corp.supernews.com>
Source record: 45873

This is kind of a bad time to ask that question. There are lots of choices, probably none of them good.

W4OP mentioned the K1 - this is a killer rig. Probably way more than you are looking for. $270 stripped, close to $500 fully decked out. Other than the 4 band option, however, there is no downside to ordering the options later. You need to build the basic rig and align it before adding any of the options, so you don't pay a price for not ordering the option right off. I tell you what, tho, the KAT-1 is really nice! But even with no options, this is a VERY nice radio.

The K2 is bigger, nicer, and more expensive.

N7XY mentioned the RH40. I have the NorCal version of the 20, which is basically the same radio without the nice case. There are few rigs at any price whose receiver can outperform this, and I assume the 40 meter is similar. This rig does have pretty high receive current for a QRP rig in order to get that receiver performance, so if your interest is backpacking this might not be your first choice. In actual operation (as opposed to the lab) this thing is a LOT better than the middle of the Yaecomwood range. Well, I say as opposed to the lab, in the ARS Sojourner lab tests it looks about like the K2 or the Yaseu FT1000MP. Only problem is, Dave hasn't been shipping them for a while and it's anybody's guess when he will start. I've loaned mine to 2 different folks. One bought a K1 and immediately noticed the receiver wasn't as good, the other bought an Icom and saw the same thing. But if you gotta have it, I'd plan for a year or so wait.

The only other one I would suggest is the SW-40+. This is the opposite end of the spectrum from the K1, this is your basic QRP single bander. Very low current draw, simple, cheap, but a credible performer. About $100 with case.

Most of the others that you can actually get are either novelty radios or older designs. Kanga has some bits and pieces that you can assemble into a reasonable rig, but it tends to get a little pricey. Ditto for the DL-QRP stuff. OHR still has some kits but an awful lot of folks seem to have to send these back to the factory to get them to work. You don't find that with the others.

You might try posting on QRP-L and/or QRP-F and see if anyone has a RH40 that they haven't built yet. Not real likely but occasionally something like that happens.

Thanks for the replies. I used my old Heath IT-11 Capacitor checker to see if there was more leakage in one direction. 10 uF 16 V was too small to see leakage on the eye tube (works fine at higher voltages), so connected my Fluke 77 DMM across the leads and disconnected one of the IT-11 leads. There was a noticeable voltage drop difference between the two polarities as the capacitor discharged. Here's what I determined:

End with indent is positive. The "Arrows" pointed to the negative end. Upon closer inspection, I noticed the capacitor consisted of a small metal can with a blue vinyl cover. The wire was connected to the can at the negative end. The positive end had a black dielectric washer - easily could have been rubber.

So, everyone's suggestion gave the correct polarity.

Howdy,

Has anyone here ever built a simple superhet using a single crystal in series as an IF CW filter. I have always wondered how well this would work and vaguely recall a schematic in which this technique was used.

Also has anyone ever tried using off-the-shelf (broadcast radio) IF filters and a double conversion scheme to get a variable bandwidth IF filter? This seems like a cheap, all mode solution.

Please let me know of the results you have had both good and bad with both schemes. I am working on a little receiver design and am considering both techniques, but would like to get some input from other folks.

Hi, Kevin,

I did a little single conversion receiver using a 455kHz resonator from Toko purchased at Digikey. It was their "AM 455kHz" model. It worked ok, but my LO drifted badly.

A lot of receivers, both homemade and commercial, used a single-crystal filter. Obviously before mechanical filters (and later crystal lattice filters) came along, but well past that time too. I gather that the single-crystal filter is what brought about single-signal selectivity in the thirties; I've seen references to a certain article (that I've never seen) that seems to be the source, at least in ham radio circles.

These were "phasing type crystal filters". The signal was split into two paths 180 degrees apart, usually by a center-tapped IF transformer. One side goes through the crystal, and the other goes through a small variable capacitor. The capacitor there is to phase out the capacitance of the crystal holder, and the result is a very narrow passband (though of course not very good skirt selectivity). By varying the capacitor, you can also a rejection notch on one side of the curve.

This was only good for CW, since the bandwidth was so narrow. Since people wanted to listen to other things, usually a variable load resistance was added. So by changing that load resistor, the bandwidth could be widened up. The better receivers would have the phasing and bandwidth controls on the front panel, and the latter would often short out the crystal for widest bandwidth, relying on the IF transformers for selectivity.

It was probably best when CW was fairly prodominent, and the bands were less crowded. Once SSB came along, there was a big shift to

mechanical filters and multiple-crystal filters, because they could provide a wider bandwidth with less trade-off, and better skirt selectivity. If you were using a filter to generate SSB, you'd have such a filter already in a transceiver, or want a matching IF in the receiver and transmitter if separates.

Usually, they've been at 455KHz, though one surplus receiver, was it the BC-348?, had such a filter at 915KHz (and from comments it didn't seem to work that well, though it might have been the specific crystal). Once in a while, someone showed a receiver with such a crystal filter somewhere just below 2MHz.

Occasionally, people would describe something using such a filter, but they would cascade a number of identical stages, for better skirt selectivity. Of course, you'd need the crystals to be very close in frequency, and then it might make sense to go to a ladder filter at this point.

More simpler, you could just put a crystal in the signal path. The 1961 ARRL Handbook shows a tuneable converter for use with a broadcast receiver, and it just puts a 1.7Mhz crystal between the output of the converter and the lead to the receiver. Not an optimum situation, but it will give you narrow selectivity with virtually no cost.

Perhaps what you've seen is in "W1FB's Design Notebook". Before going into crystal ladder filters, he suggests a couple of simple and cheap filters. One is just a 10MHz crystal in the signal path. He notes that a low IF will not have enough bandwidth for voice. Again, you'd probably get some limited control over bandwidth by adjusting the load resistor.

I don't think the scheme of mixers and multiple filters is a good choice if you are starting with not so great filters. You end up with the problems of extra conversions, and without good skirt selectivity.

I assume the ceramic filters in CB sets are narrower than what you'd find in a broadcast radio. Pick up some scrap CB sets at a hamfest, and cascade two or more filters. This would give you better selectivity, more suitable for voice (though not perfect for SSB) and better skirts. Get a ceramic resonator that matches the frequency of the ceramic filters (I'm not sure if the CB sets all use 455KHz, but I've seen broadcast receivers using either 455KHz or 450KHz). And use that for narrower selectivity. Ceramic resonators may be easier to get than crystals at that frequency; I just opened up a remote control the other day, and there was a 455KHz resonator.

Or get a bunch of ceramic resonators and try making a ladder filter out of them.

Kevin:
I tried some designs with 8 MHz IF Filters. I have a schematic of a litlle 14 MHz receiver in my web page www.qsl.net/ea6np (Go to "Homebrewing", receiver called "B14")

The IF bandwith with 6 xtal is 800 Hz, and with 4 xtal is about 1,1 KHz. This second options sounds quite well on CW.

It was a surprise to me too, but that's what the fellow claimed. It's
been 20 years since I talked to him, and it had been years since he had
worked on them, but he seemed pretty sharp on all the details.

I thought it was all military and test
>pilots. I'm not a pilot, but as I recall , and based on what you said
Jet-Paks
>could do, you really shouldn't need a pilot's license.

Hmmm, well if it weighs less than 254 lbs, goes slower than 61 mph, and
carries less than 5 gallons of fuel it could qualify as an ultralight. I
think the 5 gallons of fuel might be the hitch there.

Maybe just a License
>to Kill (Hi, Hi.)

Or crash.

Did you and your friend ever talk about building one ?

No, he was the landlord of a friend of mine in college, and he *had*
built them in the past so he wasn't interested in doing it again. Just
fondly looking back at some cool projects he'd participated in. I'd love
to have one, but feel a bit naked flying without a cage around me. I've
done it parachuting and it's sort of unnerving to just be hanging out
there. I prefer a plane or ultralight I can sit inside of.

That website posted by Kevin Ames is pretty cool too, (thanks kevin),
though it doesn't quite dovetail with my friend's account. And your
dad's history. I imagine it would be very interesting if we ever all got
a really good account of all the things that happened during that time.

Source record: 45889

Have some problems constructing an xtal filter for 60kHz, so in the meantime I will try an LC-filter using two 4.7mH coils (with 1500pF) and undercritical coupling

The filter is connected between drain of 40673 and input of NE612 using a cpacitive divider to transform to 1500 ohm. Can't find any gos for 3N200 for less than 100MHz (0.15mmho), so I suppose it is very high.
The coils have an unloade Q of 650, so the unloaded bandwidth may be small enough, but I wish to improve rejection.
0.2-1kHz bandwidth is suitable, but I cannot remember how to calculate the top capacity

any suggestion, pse?

Eamon

Have you looked into the TI TRF4400/4900. This is a transmitter on a chip with DDS, PLL cleanup and an amp (well 7 dbm so not much of an amp) for a tiny fraction of the price of the AD parts, and a bunch easier to get, at least over here.

The 4400 is a 440 MHz part and the 4900 is 900. A little division and it seems like just the thing for a VFO, altho Steve Weber did get the 4400 to work down in the 100 MHz region so for 144 MHz maybe use it direct. TI also has 1 and 2 GHz DDS chips that are real cheap and easy to get, but the 4x00 have the PLL onboard for the same price (around 3 punts, I don't know what that is in Euros).

..

Jan-Martin:

The easiest way is to use the demo version software FaiSyn available at;

http://members.aol.com/faisyn/faisyn.htm

It will automatically calculate the coupling caps for you and design the filter as well. It does top coupled resonators quite well.

If you want the details behind how you might calculate these by hand, I can go through that with you as well. It basically involves determining the normalized coupling coefficients k12, k23, etc. and transforming them into de-normalized coefficients K12, K23, etc. The k12, etc. are found from tables, or from the underlying equations (Tchebychev, Butterworth, etc.) But, all this is embedded in FaiSyn.

1852. AD607s as HF Receiver front end

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-06 03:54:53 UTC
From: Kevin Ames <mtnclimb@in-tch.com>
Message-ID: <a6440b$43p$1@news.tamerica.net>
Source record: 45894

Howdy,

Has anyone tried to use the AD607 as an HF receiver? I used one back in 1999 with an AD7008JP50 as a simple 20m superhet for my senior design in college. If anyone has had good results I would love to compare notes. I got it to work, but the results were less then optimum. I have not tried to build a superhet since and am thinking about attempting this again. This time I won't be under the time constraints and doing most of the work at 3am, so I may have better results. Anyhow, any info would be appreciated.

Kevin: Doug DeMaw had a circuit in one of his books that used one rock
as the filter. He also used a crystal to replace the emitter bypass
cap in the IF amp. I thought that was pretty cool.

Clyde,

There is already a chip (if you can find it) to convert 7-segment to BCD, the 74915. You'll still need to demultiplex the 7-segment in most cases.

I built a fantasy clock using an MM53xx (15?) chip and standard CMOS logic chips several years ago, a wall clock loosely based on the "Alien Clock" which was an LED binary clock that enjoyed brief popularity and even appeared in some episodes of Star Trek: Deep Space Nine. Interestingly, the Alien Clock had a "random" feature which gave a constantly changing display that does NOT tell the time, but in one episode a character "reads" the time from this display!

Here's the link to the NEONIXIE-L Yahoo group:
http://groups.yahoo.com/group/NEONIXIE-L/join

Hope to see you there soon!

This appears to be aimed at the market for short range remote control links.
They quote phase noise at 100dBc/ root Hz at 50 KHz which doesnt appear
particularly good.
Also, as the DDS is the reference for the PLL, spurs will not be cleaned up
much by the loop and will be amplified by the frequency multiplication.
I cant see any figures on spectral purity but I guess it is not critical for
the application.
Are there any data from the people quoted on this?

1861. Battery assisted power supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-06 16:51:53 UTC
From: post_to_usenet@hotmail.com
Message-ID: <b6b4e772.0203060851.662faea2@posting.google.com>
Source record: 45753

Hi,

I'm buying my first HF rig, and I will need a power supply for it. I was thinking of doing it myself. I know it will probably be more expensive than if I buy it, but I think the pleasure is in building it.

After thinking several options (20~30 A is more than I am used to work with), I think I'll try to do it with batteries, a small charger and a stabilizer.

Ideally I would use 3x6V to make 18V and then use a stabilizer to reduce it to 14.5, but big amperage 6V batteries are hard to find (here at least).

Then the other option is to use two 12V ordinary car batteries and go up to 24V, but the problem with this is the increassed dissipation when reducing to 14.5V (~200W @ 20A). A good thing about it is (IMHO) that, in mains failure conditions, you could parallel both batteries and run the rig at 11~12V for a longer time. Q: Do modern rigs turn off themselfs at some (un)reasonable point below/arround 12V?

The working conditions for the batteries would be simmilar to those in a car: Off most of the time; short discharge periods (TX) and charging while the rig is on RX.

What dou you think about it? I haven't decided yet, and would like to hear other people's opinions.

Thanks for answers

Toni

Toni:

Building an AC supply for your DC powered transceiver is only more expensive than buying one ready made if you insist on buying new parts and paying retail prices for them. If you look around at ham swaps you can often find the parts for a tiny fraction of their original cost...I know because I often sell them there. I have a number of homebrew supplies running now that were built from miscellaneous parts.

A battery offers some advantages, like the ability to keep running when commercial power fails, but they have a limited lifetime and have to be periodically replaced. Also, you should use "deep cycle" or "marine" batteries, not automotive types...car batteries don't like to be heavily discharged and recharged.

Also keep in mind that the term "12 volt" when applied to batteries is a name and not an electrical specification. The actual voltage can be much higher when fully charged.

If you really want to go with a battery for DC power, use a single marine/deep cycle battery with a smart charger that won't overcharge it. Don't complicate matters with multiple batteries with a wasteful regulator.

A similar arrangement was quite common when ceramic resonators first came
out. They used conventional IF tranformers, as well. The resonators gave
additional selectivity.

Jack Smith suggested a filter-specific program, which of course should work fine. Another way for up to perhaps three resonator systems would be to simply use SPICE. It's trivial to "adjust" the coupling capacitor and see the freq response changes. You can get various freeware versions of Spice, and of course it could be useful in providing insights into some of the other circuits you explore. If you're interested, and have trouble finding the freeware ones, post a query and I'm sure we can come up with some links.

Cheers,
Tom

Tom et al:

Humpreys referenced further up the thread shows the different effects of
using:

a.) Capacitive Top Coupling
b.) Inductive Top Coupling.
c.) Mixed Top Coupling, some Caps some Inductance, which ones and why,
etc...
c.) Imaginary Resistance (Constant Reactance) Top Coupling.

Each type of coupling gives a slightly different result, especially in terms
of passband ripple and symmetry.

Depends upon what you are after in the detailed passband response.

I agree, on low order systems you'r probably wasting time with synthesis,
just throw it into a circuit
simulator/analyzer and bench tune it!

Howdy Toni.....Your scheme for using an 18v battery bank, charger and stabilizer (regulator) is sound and has the good advantage of being a no-break power supply good for AC mains interruptions - a side benefit of using the 18v is obviously that you have much more time available at rated (regulated) voltage for your equipment (as you obviously know).

Not sure why you can't find 6 volt batteries, but I'd suggest the following sources.....Truck parts places.....Agricultural and Heavy equipment dealers (always carry a line of HD batteries....and, although not as common as they once were, usually have 6 volt units available or in stock). Fork lift / material handling dealers/service depots also use 6 volt units for their (warehouse usually) equipment - here you "might" be even able to find "pulls". Marine supply houses often stock or may have available 6 volt batteries as well (some marine setups use banks of 6 volt units for their batteries). Some lead-acid battery "group" numbers you might look for are as follows:
BCI groups 1, 2, 2E, 2L, 2N, 17HF, 19L, 3, 4, 5D, 7D, 3EH and 4EH.
also listed in an older BCI guide (Battery Council International) I have here is for Electric Vehicles groups GC2 and GC2H.

You might also check with your telephone company/service dept as they "might" have available 6 volt (or close) batteries though they may be physically large.

Best of luck.

now received some suggested values between 4.3 and 26pF, perhaps I'll
try passband-tuning next?

...and with my somewhat limited efforts reading old ARRL handbook I
thought 90pF would do, but it isn't too difficult to sort out when you
know it is possible for this type of filter. Had more troubles with
single-xtal filter, measured some evenings, but seems impossible
without sweep-equipment, so I'll visit to LA6LCA who has network
analyzer and spectrum analyzers which works between 9kHz-30GHz

I'm about 90% done building a tunable 450 KHz - 2 MHz 3-resonator
filter. Mechanicals almost all done, coils wound, just have to finish
the tuning knob connection to the caps.

In order to keep the passband even close to reasonable over the two
octave tuning range, I had to make the coupling caps variable and gang
them with the main tuning cap. (That part is done with a toothed
timing belt drive.)

I looked at inductive top coupling and mixed coupling, but found
impracticable values. My capactive top coupling values started out at
10pF (500 KHz) decreasing to 0.9 pF at 1800 KHz. These are a bit
tough to realize, so I tapped the coupling caps down halfway on the
inductors and wound up with 40 pF --> 3.6 pF.

During the design and simulation process, I looked at one capactive
and one inductive top coupling circuits, as it would make the passband
more symetrical. Unfortunately, the coupling inductor came out around
4 mH (which also would have to be variable). This is a rather
unreasonable value to expect to work without stray resonance over this
frequency range, so I went with straight top couple C.

It would have also been possible to do bottom coupled C, which would
have the same effect (lower coupling with increased frequency) as top
coupled L. But, this also results in impractical values as well.
(2,000 or 3,000 pF variable, as I recall.)

Anyway, I learned a great deal more than I wanted to about coupled resonators over the last few weeks.

Toni:

I've been using a single 12-V, 90-Ah deep-cycle battery and a home-made 4-A power supply as a charger for almost 10 years now. There's no need to go with the multiple batteries and regulators. You won't find better DC than what the battery will provide.

90-Ah is a medium sized battery that will run a 20-A rig for a long time. I don't know about all the rigs out there, but the Icom IC-746 (20-A transmit, 2-A receive) and Heath SB-1400 (20-A transmit, 1-A receive) both will work down to about 10.7 V. I've operated an entire Field Day weekend (with the charger disconnected) without draining the battery below 11.5 V.

Keep it simple.

I have simulated just such a circuit using Microcap 3 which was around as freeware a few years ago.
As Tom says you can just change thavalues and observe the AC response and impedance etc.

I've found RFSim99 (freeware) to be very good for resonator modeling.
It's available at:

http://rf.rfglobalnet.com/software_modeling/software/2/710.htm

It also includes a filter design module, but the filters are not
coupled resonators. The matching module may also be of some interest.

You might look at the Tentec t-kit. Fairly inexpensive, the manual is laid out to
allow for the "test as you build" method, nice looking enclosure. Have a lot of fun
with mine. It is a tad heavy if you are into backpacking, though.

CMOS switches are often used effectively in mixers, so they should be OK.

> rated (regulated) voltage for your equipment (as you obviously know).

NOT!

That would be true IF and only if he was using a switching
regulator. A typical linear reg will simply waste the excess power
as heat.

I don't think the 18v approach is worth the hassle and expense.

Now if you happen across some 2v cells (BIG batteries, e.g.
forklifts, etc.) are often sold as single cells) then use 7 cells
instead of 6 and you get a nominal 14v (14.7v full, 16.1v float)
battery. No regulator needed when not on charge, but watch the
float and charge voltage as it is a bit high for some equipment.
Floating at 15.8v would probably be OK.

But overall I agree with the "keep it simple" folks. Just use a
single marine or RV "deep cycle" (not "starting") battery. It
should float at 13.8v and run 12.6v (full) to 11v (empty) during
use. This is fine for nearly everything.

For the work I do professionally in spectral analysis instrumentation, I can use cmos switches in the signal path, but only where the load on the output side of the switch is a high impedance. The variation in switch resistance as the input voltage changes (over a cycle) results in too much distortion for my applications, if the output load is too low an impedance. (Commonly the load isn't such a high impedance, and we use relays instead of fet switches.) Other than that, just pay attention to the data sheet specs on things like capacitance and isolation. The switches rated for video applications should have enough data to make reasonable decisions about whether they will work for you or not.

Cheers,
Tom

I'm rebuilding the power supply of a GenRad 1933 sound level meter (circa 1977 or thereabouts). A couple diodes in the switcher were shot so I have replaced these. One difficulty which I encountered, however, is the paraffinic or plastic coating GR used to protect the circuitry from the elements and leaky batteries. I used Xylol (which I guess is something like an alcohol cousin of xylene) to dissolve a bit of it (so I could solder in the new diodes.) But I really don't like using these solvents within the enclosed area of my workshop. Anyone know the makeup of the resin which GR used?

1888. Old tube type Email List - No Nonsence

There is a no nonsence email list (reflector) 4 years old now.
It is for buying and selling old tube type gear and their
accessories ONLY.
No discussions, no arguments, not intended to be
friendly, nor unfriendly.
Unless an item is very unusual, prices are required.
At the present time, no annoucements of auctions.

The email list is baswaplist@foothill.net
The list is as spam proof as they get. We have not had
any spam in over a year now.
It has always been free, and contains no commercial
advertising.
We use plain text only, no HTML, etc.
Attached pictures (jpg, etc) are no allowed, however
links to them are incouraged.
Expect to receive 5 - 15 emails per day, from people
wanting to buy or sell old tube type stuff.

TO join the list:

SEND TO: majordomo@foothill.net
SUBJECT: (does not matter)
MESSAGE: subscribe baswaplist
(That is ALL you say in the body of the message.
the email address from which the message is sent
will be the address subscribed to the list.)

It's taken me a day or two to get back. I can't thank all the respondents enough. A really enjoyable read. The entire web-site was a fun read -- most new to me. I remember seeing promo films or newsreels for "Flying Cars" , for instance, that showed one sorta taxing up to a suburban home. PR by Aerocar ? Who knows.

The jet-pak/Rocket-pak info was cool, if all too brief. Tantalizing was the brief mention that "some" continue to experiment with them into today. Think next time I get bored and decide to do a late-nite net crawl I'll see what else is out there on jet paks.

Regarding "those days", there is a guy around my area (Wash.D.C.) who's working on a Cold War Museum. I only met him once or twice but we have a loose connection - He's the son of Francis Gary Powers and my dad did debrief him once or twice. I only mention this because my pop has now written a book/manuscript regarding the early days of the U-2, the SR-71, and what the History Channel calls "Project Corona". Lots of techie anecdotes. Even a UFO story that beats Art Bell by a country mile! It has recieved approval by Gerald K. Haines, Historian at Langley and is awaiting final approval from Ft. Meade. There was a time when people would've died for this knowledge -- now it's just old wars stories of 30/40+ years ago. Maybe he should call his book, "Boatanchors of Intel". (Hi,Hi.) Times changes all, I suppose.

Hope the very best for all,

KG4JBM / Andrew

1891. Re: switching RF using cmos ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-08 03:13:21 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3C882C50.FE5AA037@cox.net>
Source record: 45782

The best RF mixer switches I know of are the CMOS bus switches available from a variety of places including TI, IDT, etc. These are designed to switch microprocessor memory address lines to one of a set of memory banks. In order to keep the delay through the part as minimal as possible, they implemented a very fast analog switch to pass the digit signals directly from the input to the output.

These are much faster than even the fastest "analog switches" that can be found else where, and are much cheaper.

The TI family of bus switches are the CBT (5v levels) and CBTLV (3.3v levels). The 5v parts will handle a 4 to 4.5v pk-pk signal, which is close to your +17 dbm. Simply make sure you provide a DC bias at about half the operating voltage (2.5v for 5v CBT stuff, 1.6v for 3.3v CBTLV stuff) and AC couple in the RF signals. The switches have a series resistance of about 5 ohms and an input C of 5 to 10 pf.

There are several useful variations. The 74CBT3125/74CBT3124 has four individually controlled CMOS switches that can be used to replace the quad diodes in the typical ring diode mixer configuration. Digital logic can be used to drive the enable lines of the switches to emulate normal diode LO switching. Far less power is required to do the switching as well, allowing for high performance in low power (QRP?) receivers.

I use the dual "1 of 4" multiplexer (74CBT3253) to get quadrature DC detection for a phased DC receiver. In this configuration, the detector has about 1 db of loss.

They seem to work very well at high signal levels and are very fast. Turn on time is 4 nsec max to 1 nsec min, which in a ring mixer configuration, should limit the upper frequency to something under 100 MHz, worst case. I would expect the losses for the ring mixer case to be the typical 5-6 db of conversion loss.

If you buy any of these parts, make sure you get the SOIC package (0.05" pin spacing) rather than the more available SSOP (0.025" pin spacing) package. Dip parts do not exist (0.1" spacing). The SSOP stuff I find very difficult to use and therefore avoid whenever possible.

I actually prefer the SOIC package when building equipment because they take up much less space and are still easy to work with. Just use #30 or #32 gauge enamel covered wire for hookup. Forget using #22 stranded!

I have access to an unused UHF CB transceiver. Is it feasible (or even practically possible) to convert it for operation on the 70cm amateur band? Can someone direct me to information on how this can be done?

I've searched at some obvious places but haven't found anything other than an implication that the conversion can be done, but not any how-tos.

(No, I don't have a licence;
yes, I am preparing for the exams;
no, I have no intention of operating illegally...)

Thanks,
Michael.

It could likely be done, but I personally would not bother. It would likely be a reasonably expensive job, and wouldn't provide particularly good results - would be a low powered and not terribly useful piece of gear, and likely the sensitivity would be pretty average. Having said that, if you want to try the conversion game, you would be better off converting a commercial radio onto 70cm - good receivers, around 35 watts, and many more channels are possible (a Sawtron KG107 - or 109 - cannot remember) can (I think) have up to 16 banks of 100 channels which is more than you need, but much better than only 40 channels. Just make sure that you get a version that is capable of being reset for 70cm. Alternatively you could always just buy one - AWA RT85 radios set on 70cm were going for $50-70 only a couple of weeks ago - all are aparently sold out now, but keep your eyes and ears open, and you might be lucky.

Matt

Hi all,

Thanks for your answers.

I think I'll follow the KISS principle and go for the simplest solution:

I'll use three 12V 7AH gel batteries in parallel (very economical) and keep them charged with my old stabilized 3A power supply (wich has reverse diodes to protect it from discharging the batteries into the PSU).

They should give enought current, as we used to use them for underwater video feeding two 12V 50W halogen lamps and the camera (~10A); A new battery lasted about 25 minutes. (If anyone is interested, ordinary indoor 12V halogen lamps work very well underwater -they are "water cooled"- with the only condition of sealing the front glass joint with some epoxy and the wire connections with some silicone).

As has been mentioned it is possible that power is reduced by 10~15% by the fact of using the "12 and something" volts of the battery instead of the 13.8~14.5 nominal, but this is less than 1 dB, so it should be OK

Thanks again.

Toni

1898. Re: UHF CB to 70 cm band conversion possible?

> I have access to an unused UHF CB transceiver. Is it feasible (or
> even practically possible) to convert it for operation on the 70cm
> amateur band? Can someone direct me to information on how this can be

anything can be done, depending on what radio you have been offered decides
if its worth doing.

The Sawtron 880 for example was an easy conversion, and article even
appeared in ARA on how to do it.
The Philips FM-320 was a little more work but not impossible as there was
also a 70cm version sold as the FM-321. It would involve some retuning, work
on coils and a repeater offsett board made (which is simple), other radios
like Unidens/Electrophones would probably require more work.
When its all said and done your better off picking up a used dedicated HAM
type 70cm set with memorys, splits, direct freq readout and features,
forget old commercial radios----who wants to stuff around with a channel
chart. A dedicated 70cm set these days would be worth less than a CB anyway
as ham radio is just about dead in this country.

Another issue to consider. Hooking 12 volt SLA batteries directly across a 13.8 volt supply works fine to keep the batteries charged (a float charge). The problem comes if you ever let the batteries discharge, say to 10 volts, during a power outage. When the power is reapplied to the supply, the batteries will attempt to draw a high current until they become charged enough for their voltage to rise. If they draw more than 3 amps and your supply does not have a current limiter then you could cook the supply. 14 AH worth of SLAs will likely have a maximum bulk charge rate limit of about 2 amps. If your supply can source more than that then the batteries may draw more than they are rated for and cook the batteries (or at least shorten their useful service life). If you are bulding an unattended backup system then you should have a current limiter set to the maximum bulk charge rate specified for the batteries being used.

For an unattended system the other thing to consider is a low voltage cut out. It is hard on the SLA batteries if you were not present, the AC power was out, and the gear continued to run and discharge the batteries below about 10 volts.

I agree.

I would not trust CMOS switches in critical applications.

We had some high speed (64 MHz) digitizers (A/D, digital receiver, and DSP all in one box) here that has a CMOS switch ahead of the A/D.

The switch introduces so much distortion that the things are practically unuseable. We are now using one that does not have anything ahead of the A/D, and the difference is like night and day!

Granted, our application is more critical than the typical hobbiests, and they may be OK in less demanding applications.

Source record: 45794

Hi,

I seem to have jyst managed to repair the clubs MFJ 259 antenna analyser but, in the many halds it has passed though, the calibration pots seem to have been 'twiddled'.

I only have limited data on the beast but it appears that the 4 pots are:

1. RF level control / agc

2. SWR cal

3. Load resistance cal

4. Frequency counter DC bias- which seems to bias the i/p of the internal counter to maintain its sensitivity?

I've tried the obvious setting process- try to get the level and dc bias right then set up SWR and Load resistance with a couple of dummy loads etc- but it just won't calibrate as accurately as I would expect and the internal oscillator is easily 'pulled' by the load which, given it has two cascade buffers between the oscillator and the load I would not expect- my theory is the AGC loop settig is the problem.

Anyone have any details or done this before, please?

Getting one-off crystals made isn't very expensive. I can get them for about
10 UK pounds for a frequency like the one you are after.

Well, a 19 KHz crystal is pretty hard to come by.....

Assuming you are dividing the 4.8 MHz down to 19 KHz, why not just buy a programmable Epson oscillator for 4.864 MHz. These things are like $3.50 and if you order it before around 5 PM, DigiKey will still program it the same day.

Well, OK, looking at the headers it appears you may be in the U.K. so maybe getting it programmed in a couple hours won't be a big deal. The shipping alone will be ten times the price of the part! But maybe there's a local source. These things are awfully handy. I think there can be a little phase noise issues with them but after you've done a divide by 256 I doubt it will be visible.

Cheap man's "current limiter" == resistor, or put a 12v lamp of the
proper wattage in series, or put in a 100ft spool of proper gauge
wire ;) . If you want a max of 2 amps out of the supply, connect it
with a series resistor of 0.5ohm to 1.0ohm (a 5 watt should do
nicely) That will drop 1v-2v at 2amps, reducing the output of the
supply as the load gets too high. A lamp has the nice
characteristic of being non-linear...

> For an unattended system the other thing to consider is a low voltage
> cut out. It is hard on the SLA batteries if you were not present, the

Yup. But if present, just turn off the load.

Is there a place to buy, or way to make, like the title says, a big cumfy tuning knob -- like on a Japanese radio? I'm not worried about the electronics so much as just getting a knob that physically feels really good. One that has some weight and when you turn it rotates smoothly and has a momentum. That is if you spin it, it'll keep spinning for a little bit. I assume it'd work like some kind of optical deal, maybe like the insides of a mouse.

Anyway, is this kind of thing you can just buy? Or do you have to build it?

>A dedicated 70cm set these days would be worth less than a CB anyway

70cm-only sets would be quite old by now. Most equipment these days covers
at least 2m/70cm.

> as ham radio is just about dead in this country.

That's news to me.

So when I sit here watching amateur TV on my rabbits ears,
while simultaneously transmitting slow scan pictures of homebrew projects, I
am
actually halucinating? Very strange when I flick to receive and I see
others sending
pictures. And if one doesn't care swapping pictures, one could do PSK-31
on 20m,
or try for DX on CW or SSB. And if neither appeals, there is always a pile
of projects
to tackle.

Then, how about the hamfests - There's four I can think of in the next
couple of months,
and that's just around Melbourne? You even see people selling gear and
others carrying
equipment away under their arms from these events - is this imagination as
well?

The number of amateur radio clubs around Australia compares well with other
sporting/recreational pursuits. The network of club newsletters, news
bulletins,
websites, club nets, meetings etc is also a credit to amateurs.

IRLP has already been mentioned. This mode has already attracted good
coverage in the Age
and SMH. One could go on about the Field Day contest that local clubs are
busy preparing for,
the upcoming Radio on Rails, or the talk on amateur satellites that
attracted 90 people to the Moorabbin Radio Club just 2 weeks ago. These
people wouln't have come if they weren't interested.

This is a particularly busy time of year for amateur radio activity. If
you're saying it's dead, maybe you're not looking hard enough, or are
envious of people having more fun than you!

I've used a 455kHz ceramic resonator with a series cap to get 456kHz.
Divide by 12 (3 then 4) to get 38k which I assume you'll need for a
coder and another 2 for 19k. I've never had any difficulty with
stability and it's cheap!

two winding primary and two secondary

each winding 300 ohms, roughly

parallel them for 150 ohms, series them for 600

if you can find a place that sells reconditioned telephone systems you might
be able to get them there

what are you building that takes 8 of them?

The "some kind of optical deal" is an optical encoder. They are available at most electronic houses, and for inputting frequency (or whatever) into a PIC or microcontroller of your choice, they are pretty convenient. However, they are a bit pricey - $30-50 or so. Mechanical ones are a lot cheaper ($3-8) but they don't have the nice feel, or the resolution.

Some people with more mechanical skills than I have made them from a mouse, it's basically the same thing.

As far as the knob itself, there has been a lot of discussion of that on the various QRP reflectors. Seems like the best plan is going to the radio manufacturer and buying it as a replacement part. Knobs are expensive anyway, and really fancy knobs are expensive enough that there is apparently not enough of a market to sell them, so the really nice ones are custom made. There was a general agreement on the Elecraft reflector that one of the Yaseau models had the nicest knob, but I don't recall which model. You might check the archives. But as I recall, it wasn't as expensive as I would have expected. Seems like it was in the $20-30 range, really not bad considering a pretty plain knob is hard to come by for under $5-10 in larger sizes.

One thing to be careful of is not the part itself but the layout, particularly thin traces and punching down to inner pcb layers through vias, these can add significant inductance (which can destroy the usefulness of bypass caps if layout is done poorly).

Good idea. I'll call up Icom/Yaesu/Kenwood or somebody like that and see what I can
come up with. (And, for me, the knob is really almost the whole project, so
I don't mind dropping a few bucks for the 'optical encoder.')

A GME Electrophone TX472S, the mining industry's staple.

It sounds like doing anything to it isn't worth the effort. The idea
only occurred to me because it would be an educational project and
give me something to play with while I'm working on my Morse. At the
moment my principal interests are building things and HF.

Hi folks,
Take a j-pole vertically mounted on top of a mast.
Disconnect the feed line from the conventional feedpoint and connect
it to the centre of the 1/2wave radiating element, as if it were a
vertical dipole with a 1/4wave stub on the lower element.
would that feedpoint be the same match as for a normal dipole?.
Just a, possibly, silly idea.
cheers Mike W

Definitely wouldn't waste my time with a 472S - I used to own one, and by far it was the deafest UHF CB that I have ever used or owned, and it put me of Electrophone for a long time. There were some mods out that allowed you to put in RX freqs for the cops, but it was even deafer on those freqs - so I reckon it would be damn near impossible to hear another radio from more than a couple of Km away if you put it on 70cm. It truly was a pox radio, and I am glad that I got rid of it - still reckon that if you are keen on the project side of things you should look at shifting commercial radios onto the amateur bands - if you pick a radio that few have done this for, you will have lots of fun and games getting everything up and running.

Have fun

Matt

Cathryn

By way of a little more detail ... optical encoders come in 2 basic flavors. There are binary/bcd encoders which return a value depending on the knob position, and there are Gray code encoders. The Gray code encoders have a 2 bit output which are essentially out of phase with each other. It turns out that if you have an application like a tuning knob, where you want to increase or decrease some value over multiple turns, the Gray code is a lot more convenient. Not only does it only take 2 input pins on your controller, but the coding is a lot simpler. If the position of the knob matters, then the binary ones are better. With the Gray code, you don't know where the knob is on power up. Encoders are available with as many steps as you want to pay for, but encoders that are intended to have knobs attached (rather than being part of some machine) go up to around 256 steps. Well, Grayhill has a mechanical encoder with a 4 bit gray code output, but it's only 16 steps. For a radio tuning dial, that's not enough.

You may need to try a few to get the right feel. Not all specify the rotational torque, and even when they do, I'm not so sure I can translate that into "feel" without some experimentation. I'm guessing you are going to want to be well below 1 oz-in, but that's just a guess! I see that Bourns has an encoder with a 0.1 oz-in torque, but it costs $30 more than the same encoder with 1.5 oz-in. All the Grayhill models seem to be 1.5 oz-in.

It would be interesting to see your results of talking to Yaecommwood. I, for one, would be willing to invest something in my projects to get that nice feel.

Source record: 45825

The last few times I've tried to access the BEC website, I have had a virus warning (w32nimda). Although I wrote and advised them a couple of weeks ago, the problem was still there when I tried again today. And yes, I had cleared my cache. Anyone else know anything about this? I am using McAffee AV and it is fully up to date.

Does anybody have a cross reference list for the older Toko coil numbers, K1731 and 4921 in particular?

Please don't reply to my email address, it was getting so much spam that I've had to disable all incoming mail.

Best regards,
Dave M0CEM

Try building an oscillator from a 38.00053MHz crystal.... Divide it down by 1000 and then by two. With a little filtering, you will have 19kHz sine wave...

The crystal is available from Mouser for $.64.

There's nothing about the resistance material that makes it significantly more inductive than a plain piece of metal. So what I do is to model the resistor as a microstrip transmission line of the appropriate length, width, and thickness. If you prefer, and the frequency is low enough that the resistor is only a small part of a wavelength (usually the case), you can replace the transmission line with a pi or L network equivalent. The equivalent L and C depend on what kind of substrate the component is mounted on. For example, an 0603 resistor (or capacitor) mounted on 0.062 FR4 (dielectric constant ~ 5) has a characteristic Z0 of around 83 ohms and a velocity factor of 0.56. You can calculate the L and C per unit length (L' and C') as:

L' = Z0 * VF / c
C' = VF / (Z0 * c)

where VF = the velocity factor, Z0 the characteristic impedance, and c the speed of light. If you know the electrical length of the line in meters, you can calculate L and C as:

L = Z0 * EL / c
C = EL / (Z0 * c)

where EL is the electrical length (physical length * VF) in meters.

Using Z0 = 83 and VF = 0.56, this gives an equivalent L of about 0.24 nH. The same resistor mounted on PTFE (dielectric constant ~ 2.3) makes a transmission line with Z0 = 112 and VF = 0.76, or an equivalent L of 0.44 nH. The shunt C to ground is often significant also, so you should include this in your model if appropriate.

If the component is mounted in any other way than right against the substrate, the inductance will be higher and the capacitance lower.

There are numerous sources where you can find the Z0 and VF or electrical length of microstrip lines.

>I think I'll follow the KISS principle and go for the simplest solution:
>I'll use three 12V 7AH gel batteries in parallel (very economical) and

Do be aware that PARALLELING batteries is not particularly recommended;
if/when a cell in one of them fails, that particular paralleled TEN-volt
battery is going to "drag" the TWELVE-volt battery(ies) down and is
liable to ruin them, too. (Of course, you can parallel them safely by
using several diodes, but that causes you to lose about a volt. I've
long wished that FOURTEEN-volt batteries were commonly available!)

>keep them charged with my old stabilized 3A power supply (wich has reverse
>diodes to protect it from discharging the batteries into the PSU).

Harbor Freight (a mail-order company which has sent me as many a FOUR
DIFFERENT catalogs in TWO dys!) occasionally offers "12-volt battery
maintainers" for $7.49 plus S&H. I think I have SIX of them keeping
batteries charged around the place (tractor, emergency generator,
hamshack, electric fence, and several spare batteries). I recall they
are rated for only about half an amp, but compared to a $24 version from
WalMart which is good for 1.5 amps, they are well worth their cost!

Incidentally, I've run my entire hamshack for some twenty YEARS using
so-called "starting" automotive batteries without any difficulties at
all. I'm not a heavy operator, but the "juice" used by an hour of
100-watt HF operation is easily replaced by my trickle/float charger
between operating sessions.

Two of those are standard "din" connectors and are available from Mouser,
Digikey, and probably RadioShack. The 13 pin plug is harder to find. They
are available at most hamfests. Surplus sales of Nebraska also has them.

Thankyou Roger, I want to, because its for a mobile aerial that has to
be above the roof line of a trailer, the mast, which is bolted to the
trailer hook, gets a 1/4wave whip in its end-cap with the coax fed up
the middle of the mast - a requirement for security of the coax - ,
the lower 1/4wave and stub isolate the rest of the mast making the
1/4wave plus mast into a verticle 1/2wave with no groundplanes - a
requirement for safety .
A transformer fed endfed 1/2 wave or 5/8 wave is mechanically less
robust, AFIK needs a groundplane and at the height it will need to be
at liable to destruction on low flying trees.
I was concidering a Ringo Ranger type arrangement, but I can't find
any dimentional details on the web.
I hope this explains my reasoning.

Hi,

I have ICOM IC-751A HF rig. I have planned to use it like a qrp rig so that I take TX-signal out from transverter jack to the external amplifier. But what is right way to make the connections? How about this:

- From transverter jack connection to ext. amplifier.
- +8 volts to pin 11 in accessory socket to disable HF finals
- Received signal to receiver input jack from external antenna switch, wich is controlled by signal from T/R control jack.

Looks like the new bus switch series devices would do well
Has anyone tried the TinyLogic series eg Fairchild
NC7SB3157 SPDT switch?
I am thinking this could be used in a balanced mixer - due to the double
throw action it would be inherently balanced
Could two of these look like a diode ring mixer?

Steve,

Know what you mean, but I believe that if
you go to the ARRL web site, you can
request reprints of articles from QST.

I don't know if you need to be a member
of the league to request re-prints or not.

Good luck on your quest, and ignore the
buttheads. For some reason, our
hobby attracts more than our share
of humanities misfits.

1960. Unusual AM Receiver Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-10 23:10:10 UTC
From: Jim Weir <jim@rst-engr.com>
Message-ID: <u8npuk77l2fuf5@corp.supernews.com>
Source record: 45700
Cross-posted to: rec.aviation.homebuilt,sci.electronics.design,rec.radio.amateur.homebrew

There is a rather unique aviation navigation signal (localizer and glide-slope) that utilizes AM modulation. At dead-center on either the runway centerline (localizer) and on the correct angle down to the runway (glideslope) there are two low audio tones that are equal. The tones are 90 and 150 Hz. As you drift away from centerline one way (or drift away from the glide path) one tone or the other will predominate, depending on which way you are drifting. Rectifying these two signals and driving a left-right meter (localizer) or up-down meter (glideslope) lets the pilot literally "fly the beam" down to near the ground.

The classic way of doing this is by having two independent receivers, two detectors, and two meters. The localizer frequencies are between 108.1 and 111.9 MHz., and they are "paired" with glideslope carrier frequencies in the 330 MHz. area. That is, for a given localizer frequency, there is a predetermined glideslope frequency.

Since things on an instrument approach happen somewhat slowly, it seems to me that a single receiver that was timeshared for (say) a second on the localizer and then a second on the glideslope, back and forth, would save well over half the complexity of the design. Not only that, but since the AM tones are the same for both localizer and glideslope, it also seems like a relatively simple sample-and-hold would work to let us use one set of filters/detectors to do the amplitude comparison. Two "meters" of course (LED lights work well) but a single receiver chain.

Here are some random thoughts...if anybody else cares to weigh in with some others, I'd appreciate it.

1. The receiver can use the same local oscillator if the first IF is high enough. If we postulate, for example, a 70 MHz. LO, the VCO only has to swing from 178 to 260 MHz. That's wide, but certainly doable. Then the synthesizer can be switched in a few milliseconds from one frequency to the other.

2. The AGC is going to be an interesting challenge, in that it will have to be a relatively long time constant so as not to lose the fairly low audio frequencies, yet fast enough to settle within our one second time sample.

3. The chips that were available the last time I did an AM design are no longer around. If anybody knows of an AM chip that will work up at 70+ MHz. as the IF strip, I'd sure like to know about it.

Thoughts appreciated.

I'm not quite clear.

Are there 2 tones for Glide and 2 tones for
centerline or 1 tone for each?

I think it would be a very suitable for a DDS with
DSP. Most DDS's have at least 2 frequency registers
so you could switch frequencies instantly for the mixer
and then run an FFT or DFT with the DSP to pick out the
tones and their amplitudes.

In fact, the Narco NAV-122 receiver, which has been around longer than
the dirt behind my instrument panel, is a time-shared LOC-GS receiver.
If you pull out the IDENT knob to engage the ident audio filter, the
GS needle drifts up and parks at the top of the dial, and the GS flag
comes back into view, warning you that GS navigation is not available.
They beat you to it. This is described in the installation and the users
manual.

Yeah: sounds like switched front-end bp filters, DDS LO, direct IF
sub-Nyquist digitizing, DSP from then on. Very few chips and tons of
code.

Has anyone tried using the new TinyLogic switches in a mixer? eg the
Fairchild
NC7SB3157 SPDT switch?
I am thinking this could be used in a balanced mixer - due to the double
throw action it would be inherently balanced
Could two of these look like a diode ring mixer?

Is there any published or unpublished design information on what time slices they took? Or what the frequency scheme was?

One thought that came to mind after I scribbled what I did this afternoon was to actually make the localizer receiver the IF strip for the glideslope. Since the pairing of the loc-gs frequencies does not appear to have rhyme nor reason, the lookup table can as easily be programmed to take into account a wandering IF frequency somewhere from 108 to 112.

The problem, then, is one of switching the antenna from one port to another. Since a quarter-wave at LOC is a three-quarter wave at GS, the same antenna will serve nicely for both.

Does the installation manual go into any details? I never have been one to reinvent the wheel when a bit of hard-won information is at hand.

Do you have any technical details of the 122? Time slice? Frequency
scheme?

One thought that came to mind after I posted this afternoon was that the LOC receiver could easily serve as the IF receiver for GS. Since the localizer-gs pairing is about as random as you can get, I'm going to have to use a lookup table to program the synthesizer anyway. Nothing prohibits me from following a wandering IF frequency from 108 to 112. I don't know if Narkie did it that way, but it seems like it is worth investigating.

One problem doing it this way is that the antenna is going to have to be switched from the LOC input to the GS input during GS measurements. Since the antenna is quarter-wave at LOC and 3/4 wave at GS, you can use the same antenna for both.

> If you pull out the IDENT knob to engage the ident audio filter, the

>
> Are there 2 tones for Glide and 2 tones for
> centerline or 1 tone for each?

Take a frequency between 108 and 112 MHz.. Generate 10 watts of it. Split it into two parts. Modulate one of the parts with 90 Hz. and the other part with 150 Hz.. Send each of the parts to their own moderately directional antennas which are pointed (respectively) 10° right and 10° left of the runway centerline. If you are down the centerline, you receive equal parts of 90 and 150 Hz.. However, as you drift right or left, you move more into the center beam of one of the antennas, and the decoded signal has proportionally more 90 or 150, depending on HOW far you are off, and in which direction.

Now, take another frequency between 325 and 340 MHz. and do the same thing, only this time orient the antennas so that the beams are pointed UP at about a 3° angle instead of sideways. Now if you are too high you get too much of one tone, and low you get too much of the other.

That seems like a lot of work instead of a PIC for the synthesizer and an opamp analog filter. This technology was invented in the 1940s and isn't sophisticated enough to go to all this trouble. However, I'm willing to learn. Wanna explain a bit how each of these would lend themselves to the design easier than doing it analog?

Well a DDS like the ADI AD98xx series could be

http://www.analog.com/productSelection/pdf/ad9830.pdf

be a digitally programmable mixer letting you precisely
pick the frequency in 108-112 MHz range or the
325- 340 MHz range with great precision.

Now you can mix this down to DC or use another DSP
trick of sub-sampling which John refered to as
"direct IF sub-Nyquist digitizing". In this case you use the
ADC as another mixer. You sample the IF at a sub-Nyquist
frequency so low that the IF gets aliased down to DC. This
avoids many problems of more mixing stages and has
become a very common technique.

Now aliasing used to be viewed as a bad thing because it
was viewed as mixing higher frequency noise on top of your
signal. But if the only signal of interest is the higher frequency
then you can use it as a mixer. But now you have to worry
not only about frequencies above the signal aliasing in but
also the frequencies below that you are going to alias on top
of (the lower frequecies). So instead of a low pass filter
you use a bandpass filter centred around the frequencies of interest.

Now, after mixing down you could look for the 90Hz and 150Hz using
an FFT. An example would be running a 64 point FFT with a bandwidth
of 240Hz. You sample at 480Hz (twice the highest frequency) and then
every bin (frequency) is 3.75Hz apart. The 24th frequency is exactly 90Hz
and the 40th is exactly 150Hz.

To simplify the analog bandpass filter you could oversample with the A/D
and use a digital filter to filter.

The name of the game is trade off the precision caps/resistors (which never
really drop in price much) and have accuracy in the 1, 2 and 5% ranges for
digital processing (which continuosly gets cheaper and better). The
precision of the circuit is dictated by the oscillator (parts per million
accuracy)
and the number of bits you specify. Compared to the analog solution the
unit to unit variation is incredibly tight and doesn't really vary with age
or temperature.

Many DSP's have almost all the functions you need built-in. They have ADCs,
DACs,
GPIO etc. It could do the FFT, the AGC, drive your audio out, do the tuning,

drive
the display etc.

In the MK-7 radar [ALL VALVES] we had a procedure whereby we were able
to stay locked on a target. It was a sort of multiplexed lobe
switching arrangement. It would appear that with todays technology a
lobe switching receiver would easily provide both azimuth and
elevation corrections NO PROBLEM.

Hey guys..

I have a NTE470 RF power transistor sitting here that I wanted to put to good use. I'm wondering if anybody knows of a schematic that uses this part. It is a 100W RF power output transistor,2-30Mhz range.

Any ideas?
Also,if anybody desperatly needs this part,I would be willing to sell/trade cheaply.

Thanks a bunch! Patrick.

These would likely work very well for that purpose. Just remember
to DC bias the inputs to one half the supply voltage.

Hi,

Well, my intention is not to use it without mains supply, and never unattended. The fact of being capable to work without mains supply would only be a side benefit.

Regarding the use of a lamp, this is approximately what I had thought about: a 10~20W 6V lamp should be just OK as a NTC, plus, if a short circuit occurs, it should fuse with the 12V and protect the power supply. Apart from this, the power supply works on a ï¿½theoreticallyï¿½ thermally protected regulator.

1979. WANTED: how to homebrew a better SWR noise bridge

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-11 15:49:44 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203110749.7c597dd0@posting.google.com>
Source record: 45721
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I have an MFJ-212 Matchmaker, a noise bridge device I use to adjust my tuner or antenna for minimum SWR. I turn on the Matchmaker, and I can listen to the noise on my transceiver. To minimize the transmiter SWR, I adjust my tuner or antenna for the minimum noise level (as heard from the speaker or as seen on the S meter).

Can anyone here explain how such a noise bridge device works? I have seen a few circuit diagrams, but I would like to know what various parts of the circuit do. (I know there is a small, low-powered transmitter that sends out a fraction of a watt at a wide range of frequencies. The forward voltage and reflected voltage have to be measured. Etc.)

I have just thought up a project: a better SWR noise bridge. I do have a few gripes about this device, and this is my inspiration to build something better. (This project will also give me much-needed practical experience with RF circuits.)

First, I'd rather NOT rely on listening to the transceiver speaker, as signal spikes (whether from noise spikes or other hams transmitting) make it challenging to tune for minimum noise from the noise bridge. I want my homebrewed SWR noise bridge to have its own speaker, which I guess would be less sensitive and would be driven by the SWR ratio and NOT connected to the antenna or transmission line. An alternative is to use a series of light bars/LEDs, analog meters, or a digital display to show the SWR.

Second, I'd like my homebrewed SWR meter to allow for both coarse and fine tuning. The MFJ-212 Matchmaker is very crude - I cannot distinguish between an SWR of 10 and an SWR of 100. Even an SWR of 5 doesn't sound that different from an SWR of 100. Since bandwidth can be VERY narrow on the lower bands (like 40m and 80m), this crudeness is frustrating. I would like my homebrewed SWR noise bridge to have several different modes, such as a crude mode to be used for SWRs over 100 (so I can tell I'm tuning in the right direction on 80m), a coarse mode to be used for SWRs under 100, a medium mode for SWRs under 10, a fine mode for SWRs under 5, and a super-fine mode for SWRs under 2.

The MFJ-212 Matchmaker has some characteristics that I do like and would like to duplicate, however. One is its ability to easily handle at least 100 W (supposedly, as I'm not in the habit of testing this) if you accidentally transmit. Second is the ability to bypass the noise bridge circuit by turning the device off (as I would rather not test its ability to handle 100 W). Third is the use of a 9V battery (which gives me a way to use up partly-used smoke detector batteries).

What does it take to homebrew circuits for VHF, UHF, and microwave frequencies? From what I understand, the higher the frequency, the greater the impact of stray capacitances and inductances as the wavelength contracts to the point that it is no longer much larger than the electronic components. I guess this is part of the reason why there are fewer SWR meters and antenna analyzers commercially available for VHF-and-up as compared to HF.

What does it take to overcome the impact of stray capacitances and inductances? More careful construction? Stripline? Anything else?

I replaced my battery a couple years back in the TS440. The original
lithium battery has the leads welded onto its case. The approach I took was
to order a battery holder from Mouser and used a lower cost and more
available leadless battery obtained from Wal Mart. I don't recall the
battery number but it was one of the common ones they stocked.

Jim, and anybody else who's interested

About ten years ago I designed a remote control unit for the Kenwood TS-140, little brother to TS-440 which supported a subset of the 440 commands. It used the good old 8051/8031 processor, a 3x4 keypad and a 2 line, 16 char LCD display. I also used a 2764 EPROM, a 74LS374(373?) chip for multiplexing the address/data lines and a 7404 for inverting and driving the serial data lines.

This controller did the following:
Displayed frequency
active VFO, A or B
RIT offset if active
rig transmit or receive status
Whether in split vfo operation or not.

From the key pad you can:
change frequency
Select VFO
enable/disable and modify RIT offset.
Enable/disable scan mode
Up/Down frequency like buttons on mike
select mode
Enable/Disable split VFO operation
Select a memory channel

I to have been playing around of migrating it to a PIC.

But, if anybody is interested, I will supply code and a schematic. Even if it has a higher chip count, only two cheap chips for external EPROM, the design is done and working. If you are interested, drop me a line. I may even get industrious and put the schematic in electronic form and put it and the code on my web site.

Jim, I'd be concerned about what the front end of this receiver would
have to put up with. With FM broadcast stations on the low side, and
TV broadcast transmitters in between, you'll need an awfully strong
front end to avoid IMD problems. In other words, a strong JFET or DBM
mixer with lots of LO power would be advised if you're thinking of
this scheme. The two receiver method avoids this headache by having
two separate front end systems with filtering on each band.

Also you'll need to be much more careful to keep phase noise within
reason. With two separate VCOs the opportunity for noise to become a
major factor is substantially reduced.

As for AGC, why bother? Why not use audio DSP to detect and rectify
each tone? Nobody really listens to this stuff for high fidelity.
Put a crude limiter on the monitor audio...

I think reason why you haven't seen your scheme before is because
although it's not all that hard to do, it would be hard to do well.

I think you already list the significant attributes; but in a nutshell
it is a white noise generator (white noise meaning a broadband
emission of RF - from ELF to low VHF).

Being better means one of two things: more power, or better white
noise characteristic. It is highly unlikely you need a better white
noise characteristic (if the bridge works at any frequency, it works
just at well at all frequencies).

Hi Jason,

Nearly all that you ask for above is a product or problem of your rig. The noise bridge approach is the simplest, (arguably) cheapest alternative to on-air tune up. An even simpler and (unarguably) cheaper method would be to use on the air signals. The problem here, solved by the white noise source, is there may be no signal, the signal may be variable for many reasons, the signal may drift and so on. The white noise source on the other hand provides a fixed level signal at ALL frequencies that is usually greater than over the air signal levels.

However, as to this last, in a 3.2 kHz band with at ANY particular frequency we are talking about a total noise (frequency) power of -73 dBm for an S-9 reading (if, in fact, you experience it at this level). This is a far cry from a fraction of a watt nearly 100 dB away; and this disparity reveals how the power is divvied up along the RF spectrum.

If you want to improve your bridge, it would be to bump up the gain to 1W or add a wideband 10dB gain amplifier. As simple as this point may seem, it will definitely test your self-challenge:
>(This project will also give me much-needed
>practical experience with RF circuits.)
Building stable wide band amplifiers is the bed rock of RF design. You should have a copy (or good treatment) of H.W. Bode by now(?).

It could also serve as the basis for many simple Shack radio standards. My white noise source consists of a weakly, LED illuminated, Photomultiplier Tube terminated with a 50 Ohm resistor (the apparent source as the PMT is a constant current device). This provides me with a white noise bandwidth out to >1GHz.

Hi Jason,
My experience has been that using 'dead bug' construction (also known as 'dirty') works very well up to 1.5GHz and perhaps higher. Lead length must be reduced to a minimum (zero if possible) and this type of construction allows for this quite well.

Hi Jason,

Modularize your stages or functional blocks: mixer on one board, VCO
on another board, MOD/DEMOD on yet another and so on. Shield each
module (should go without saying). By pass power and control lines.
Observe proper grounding techniques.

Actually, the last point about observing proper grounding is the most
difficult to implement. The failures to observe are found in ALL the
common design problems (coupling problems, birdies, instability,
offset, noise...). Modularization tends to increase this hazard, but
mono designs do not fare much the better.

You also need to characterize each module. Build and test it to
complete specification. It is highly likely you want to preserve your
investment; then make it generally useful. For example, design the
mixer board to a spec that is more easily met across a spread of
applications you might want to test it in. This means that most I/O
will be designed around the 50 Ohm standard. You will already find
that most commercial packages anticipate this.

What you already describe as difficulties can be limited to the module
board and the problem isolated to an obvious source. Most UHF/SHF
design is quite intuitive and straightforward when you consider the
geometries and wavelength. On the other hand, there are greater
difficulties that arise from the complexity of the modulation, or in
the control of AGC (or its application). That is to say, there is

usually more grief to be found in the "system" signals than in the RF path.

Cross-modulation could be a serious problem indeed. But a low-gain r.f.
stage with *input* tuned circuits for both frequency bands would be a
feasible solution.

Except that this part, and indeed most parts of this genre have an upper frequency limit of 50 MHz.. I did a pretty thorough job of scanning the data sheet for tricks to get it to operate up in the 100 and 300 MHz. region and didn't meet with much success.

>
> Now you can mix this down to DC or use another DSP

That's why we design in at least one variable component. Yes, they age, and yes, they need occasional calibration, but a 2 cent 5% capacitor still isn't anywhere near the digital processing cost.

And I'm still trying to search the literature to find one that will work in
VHF. Any suggestions?

Jim

OK, I can see that a white noise generator wouldn't work here. I
guess some type of miniature signal generator (with a knob or other
control on the device) is needed to ensure transmission at just one
frequency.

The white noise signal isn't always much greater than over-the-air signals. The over-the-air signals can be significant on 40m and 80m at night. And while my radio does have an attenuator, this affects the white noise AND the on-air noise.

> FFT after you do the messing around to select the proper frequency
> component.
>

For each frequency bin in the FFT:

Power in dBm = 10*log10(I*I+Q*Q)+13.01

where I and Q are the inphase (real) and Quadrature (imaginary)
components of the FFT output. 13.01 is the 'magic number' to convert
to dBm, assuming a 50 ohm load. You will have to use a different
number if the circuit impedance is not 50 ohms. If the time domain
input is a real series, as opposed to complex numbers, the signal will
show up in two places and you will have to add 3 dB to the above
value.

If you want voltage magnitude, volts = sqrt(I*I+Q*Q)

For the frequency component, assuming the typical fft output with 0
frequency in the first bin:

Frequency of bin = (Bin Number) * (a/d sample rate)/(number of
samples used)

The first bin is numbered 0, etc. 'number of samples' will be a power
of 2.

Without writing a book on FFTs, this should get you started.

For the first questions, have a look at some of the very good postings
that have been made on how directional couplers work. You should be
able to find some in the Google archives. For example, I posted one
explanation back in 1992 under the title, "A (long) look at SWR &
directional pwr mtrs" that you should be able to find. But there are
plenty more of them...some other by me, many by others.

One thing to consider in building your dream tuner-tuning aid is that
noise excitation is very broadband, and you ultimately need a circuit
that's more narrowband than the tuning you're trying to achieve. Your
receiver does this for you with a noise bridge: you only listen to a
small piece of the spectrum. If you're going to have a speaker in
the tuning aid, you might consider using narrowband excitation instead
of narrowband detection.

There've been some articles on using the very sensitive Analog Devices
logarithmic RF detectors to measure SWR. You should probably have a
look for/at them. Some of them probably come very close to what you
want. Actually, one of your complaints is that it's hard to tell that
you're getting closer to proper tuning when you're a badly de-tuned.
You could help that a LOT if you displayed not SWR but load impedance.
There's a lot more info about how to tune if you know the line is
presenting 2 ohms, or 5+j61 ohms, or 1250 ohms...all about 25:1 SWR
(to a 50 ohm system).

Cheers,
Tom

If the distance between the two signals is always the same, how about planning the VCO frequencies such that all you need is a high-pass and a low-pass filter to receive either frequency? That way you don't need to re-tune the VCO, you simply switch your VCO signal from the high-side mixer to the low-side mixer.

Just a thought.

I was wondering whether it is possible to build a superhet type receiver
but using a digital mixer for the LO and incoming signal, i.e. an XOR
gate. I can get hold of a fairly useful programmable PLL chip from work
which should work as a suitable LO, although it may need a bit of
dividing down.

Is there a way to get the input signal into a suitable digital form?
Will the XOR mixer work?
What do you do with the resulting signal?

regards...

I guess I wasn't as clear as I might have been. The pattern of glideslope frequencies has no regular mathematical relationship to the localizer frequencies. That is, (for example) 108.1 is paired with 334.7, 108.3 is paired with 334.1, 108.5 is paired with 329.9, 108.7 is paired with 330.5, and so on. It would appear as though somebody sat down with a random number table to do the pairing.

We have been having a discussion on the use of CMOS switches for this purpose. I think you would have to have a linear path for the RF signal. A digital device would have to be biased to its linear region unless you are happy with square waves in and out...

Dan
I am trying to visualize how they would be connected.
Two of them could be made to look like a ring mixer (I think) but I am not exactly sure how it all goes together
I guess it would look like input->3dB hybrid splitter->2 single ended inputs. Outputs cross connected (ie 1A+2B and 2A+1B) to a differential input device (eg opamp or balanced transformer). LO switches at 180 degrees
They are very small (SSOP size) 6 pin devices
It may be difficult getting them in hobbyist quantities.
What do you think?

Bob and Richard's advice is spot on. Solder components directly to bare copper board and minimize their lead lengths. Modularize everything (SMA jacks and the Hammond 1590-series boxes are your friends). And watch out for ground loops (I would not put a VCO in its own chassis, because you will NEVER get the ground currents out of the tuning line).

Ugly construction is usable to 2 GHz easily. If you keep your connections under 1/10 wavelength or so (~1 cm at 2.4 GHz), then you can avoid a lot of the nasty transmission-line behavior that people usually worry about at these frequencies. Just rely on 50-ohm building blocks as much as you can (if Hammond is your friend, then http://www.minicircuits.com is your next-door-neighbor who works for Victoria's Secret), and plan to give up about 0.5 dB per device due to VSWR.

There are a few photos of hand-wired VHF-to-microwave projects on my site (below), including a complete synthesizer with 1 Hz resolution between 1 and 2 GHz that fits in a single 4x2x1 Hammond box. The ugly RF wiring is completely buried under other parts, but it's there.

If you need just a bit higher performance than some of the minicircuits
stuff, you might want to try www.stanfordmicro.com. They even oem
some of the minicircuits stuff. Richardson in the US distributes their
stuff, and it is readily available.

One part of note provides about 1.6dB NF, and has better than 10mw output
power. It is also SiGe which will do better in some cases (e.g. LF noise)
than more aggresive PHEMTs.

There is a designers kit for Stanford micro stuff, that also includes some fabricated PC boards to build example circuits.

Well there are several ways to handle this.
You have to do some analysis and tradeoffs.

Read something like this...
http://www.intersil.com/data/an/an9/an9509/an9509.pdf
and this.....
http://www.analog.com/productSelection/pdf/AD6620_a.pdf
and this
http://www.hunteng.co.uk/solutions/digitalradio_sol.htm
and this
http://www.ece.jcu.edu.au/eric/thesis/DigitalRx/txdr01specs.htm

to get your mind thinking of other ways of doing it. The bandwidth
(not the frequency) you have to handle is small and contains little
data. That makes somethings easier. Many ADCs are now spec'd
for IF use. In the old days (> 5years ago say) they assumed Nyquist
sampling and often didn't spec. analog bandwidth beyond 1/2 the max
sampling rate (or they deliberately limited it to reduce noise). Now they
realize people are using it for downconversion.

Look a this datasheet
http://focus.ti.com/docs/prod/productfolder.jhtml?genericPartNumber=ADS2807
50MHz sample rate but an analog bandwidth of 270MHz.

You only need to use your the DDS to span the tuning range which in
your case has a 15MHz span (325-340MHz). You could put a fixed
downcovertor in the path and use a DDS to tune in the final frequency
that the ADC will do the final fixed downconversion on. Or you could
vary the ADC clock. There are also digital mixers so you mix it after
it is digitized.

I use to design cable modems that ran up to 750MHz and with a DDS
that couldn't clock higher than 50MHz. Which reminds me, the frequencies
you are using are in the Cable TV band. You could whack down a dirt
cheap digitally programmable TV tuner to pull the data down to a frequency
the DDS could use. But be careful of microphonics. The vibration of TV
tuners can through off the tuning (could be OK in this application) and I
expect planes to vibrate alot.

> --Gary

But what would be the advantage? An XOR doesn't strike me as anyting
special in the way of a mixer. You see it used when there are already
digital signals, though what I recall the signals have been oscillator
outputs. And you have the trouble of making the conversion to digital
before you can use such a mixer, and then deal with the digital signal
later on in the signal path.

The one "digital mixer" that I always thought intriguing was a "Type-D
mixer", ie a type-D flip-flop, that acts sort of like a low-pass filter.
There might be use there, but I don't see it worth the trouble of
doing a conversion to digital first.

You can find plenty of mixers that will work with a square wave signal,
indeed expect a square wave signal. If nothing else, people have used
CMOS switches as mixers, and they need a square wave for clocking. So
you use your PLL to clock the mixer, but the analog signal from the
antenna remains analog.

I see on second reading that you ask what to do after the mixer. That
indicates you are only looking at the mixer. There is no point in
doing this unless there is a specific reason. It is much easier
to do a conversion to digital lower in frequency, and even after some
sort of filtering. And I can't see a point of a "digital mixer" unless
you were committed to a digital scheme through the rest of the receiver.

You're question is too broad. VHF is considered to start at 30MHz, right next door to HF. It's an arbitrary division. If you are working at 35MHz, or even 50MHz, construction will be almost identical to construction in the HF range. Of course, you can be sloppier at 3MHz than at 30MHz, and as you move upward in frequency, you have to be more careful. At 144MHz, you have to be more careful, but there is no real difference in construction techniques. It's only when you get up into UHF and more so microwave, do you start using radically different construction techniques.

I think over the years, the definition of difficult construction territory has move up in frequency. Forty years ago, you'd see people writing in the ham magazines about how difficult it was to build at 220MHz. But as the higher frequencies became more common, and devices improved, people would only start to say such things when dealing in 432MHz or higher. In the tube era, things were pretty bulk, not just the tubes but the peripheral components. When transistors came along, things became smaller, and the fact that transistors weren't as heavy as tubes and their peripheral components meant that it was easier to make things smaller. Even forty years ago, you'd have to struggle to get good noise figure in a UHF receiver, scrounging some special part and tweaking it. The devices have gotten better, so at the same frequencies less effort is needed to get to the same level.

As for commercial equipment, I don't think difficulty of construction is an issue. Far more people have traditionally been on HF, hence there's a bigger market. Even if there now may be more using VHF than HF, the needs are much simpler. There will be few working on really complicated antenna systems, so the market will be limited on fancy antenna test equipment.

They can give away cellphones if you sign
up for cellphone service, which should be an indication that it's
not all that much trouble to build at VHF and UHF. A cellphone is
much more complicated than antenna test equipment or a simple transmitter,
yet there is no problem in manufacturing them in enough quantities
that they are given away.

2008. Need grid-dip reference circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-12 06:16:10 UTC
From: Gollywog <_eng@ilos.net>
Message-ID: <K2hj8.1234$8i2.32461@news2.mts.net>
Source record: 45649

Anybody:

I need a little micro controller circuit to help me tune a bunch of LC networks to resonance. If anyone has seen a public domain project which fits the description below I'd appreciate a pointer. Otherwise I'd appreciate comments on the strategy indicated in the block diagram at:

http://www.ilos.net/~eng/index.html

I want to borrow from the classic grid-dip meter approach and loose couple to a variable frequency oscillator (VFO) then look for a change in signal level as the VFO is swept past the network's resonant frequency. I do not want to use the classic approach of coupling directly to the VFO's main (frequency determining) inductor. I also do not want to use the classic approach of trying to cause a large change (i.e. dip) in the VFO's output level. These last two ideas seem to invite instability.

The distinguishing characteristic here is the use of a second "receiver" coupling loop instead of the classic design approach of monitoring the VFO signal directly. The idea is that the variable gain amplifier driving the "transmitting" loop and the RMS-to-DC converter and error amplifier following the "receiving" loop complete a closed system that attempts to maintain a constant signal level at the "receiver". The ADC connected to the error amplifier output provides the MCU with on demand access to the gain level being used at the VGA. Operation involves an initial "calibration phase" frequency sweep to plot a baseline coupling curve, then the LC network is brought in and subsequent frequency sweeps should show the "dip" (from the energy being coupled into the LC network's losses) as a "bump" in the difference in the drive levels required at the VGA over frequency.

I am especially interested in any public domain work which addresses the math behind introducing the parallel LC network under test into the vicinity of the "transmitter"/"receiver" coupling field. This seems to be beyond the modeling capabilities of EZNEC and I really don't understand 4NEC2 and WIREGRID well enough to even try. Something on stability (i.e. poles and zeros, etc) in a circuit like this (i.e. where everything is converging toward DC), would also be helpful. I don't see the point to adding a ferrite rod, etc at the moment but I'd be interested in any comments w.r.t. the pros and cons.

Thanks,
Mike

I have a local noise problem I am hoping someone can help me track down. I hear

S-6 or 7 loud, 'coarse' has on all HF bands, on all frequencies, though the intensity of noise diminishes somewhat on higher bands. On 40M, my main band, it is all but intolerable, making QSOs with all but the loudest stations difficult, even at 12 WPM or so.

The noise comes on for exactly 2' 15", and goes off for exactly 1' 25". Over and

over. I have timed it many times over two weeks. The noise is only there after dark. Aha! But I have searched and searched for an intermittent streetlight, to no avail. I have gone about three blocks in all directions from the house in this search, and also looked for automatic driveway/porch lights nearby, but can't find any. What the &*%$ can this be!?? I am really puzzled by the exact timing, since it would seem that a streetlight malfunctioning wouldn't do this, and a driveway light might stay ON for a specific time, but not off! HELP!

I doubt this will help much, but there was an article in 73 Magazine, probably 1978 or 1979 (there is no date on the pages) by Walter van B. Roberts W2CHO/K4EA. (W2CHO is no longer active, and K4EA is not him.) The title was: "New Life For Your Old Dipper," and he goes through a couple of permutations ending up with:

"It was only after trying to do it the hard way that I suddenly realized that . . . the problem of eliminating direct coupling between transmitter and receiver could be solved by putting electrostatic screening around the transmitter so that it put out only a magnetic field, while the receiver was made to be sensitive only to an electric field."

Fortunately, the component size has been reduced over the years from
tubes to discrete transistors and the surface mount components. Since
there is no longer a need to mount leads through the PCB, the stray
inductance can be greatly reduced, thus, more or less traditional
designs can be used well into the UHF range.

>I guess this is part of the reason
>why there are fewer SWR meters and antenna analyzers commercially
>available for VHF-and-up as compared to HF.

On HF, where the feed line losses are quite low, there is not much
interest in tuning the actual antenna, but instead try to resonate the
combination of the antenna itself, the feedline and the antenna tuner
as a single unit. If you measure the complex impedance at the lower
end of the line, it does not tell much about the antenna terminal
complex impedance, unless you know the exact feedline electrical
length in wavelengths for that particular frequency, due to the
impedance transformation of the unmatched feedline.

On VHF/UHF, in which the feedline loss is usually considerable, the
SWR meter will give smaller indications at the low end of the
transmission than at the antenna terminal, so you must know the
feedline losses to compensate for it. Anyway, due to the considerable
feedline loss is, part of the forward as well as reflected power is
dissipated (into heat) in the feedline, thus, it not a good idea to
match the VHF/UHF antenna with an antenna tuner down in the shack. The
proper way is to match the antenna itself, which requires that you are
able to measure the actual impedance at the antenna terminals. Thus, a
proper VHF/UHF antenna analyzer would have an outdoor unit at the
antenna (a directional coupler with rectifiers) and in-house unit for
displaying of the measured values.

>What does it take to overcome the impact of stray capacitances and
>inductances? More careful construction? Stripline? Anything else?

If you are used to working with complex antenna impedances, adapting to micro striplines should not be too hard. Various stubs can be constructed from sections of PCB tracks. The velocity factor of glass fiber boards are about 0.5, so a quarter wave section is about 90 mm at 432 MHz and 30 mm at 1.3 GHz, so it should be quite easy to work with these. At 432 MHz, the dimensions are of course a bit bulky for portable applications.

An low power amplifier with both 50 ohm input and output impedance can be constructed by first making a 50 ohm strip and cutting it into 4 parts with three cuts. Across the first and last cut, install SMD DC blocking capacitors and at the middle cut, install e.g. a MAR-x series MMIC amplifier and a bias resistor to supply the operating current. Install SMA connectors at the ends of the stripline and you have a modular amplifier with 50 ohm input and output impedance.

John Miles wrote:

> Modularize everything (SMA jacks and the Hammond 1590-series boxes are
>your friends). And watch out for ground loops

Grounding is a potential problem with diecast boxes because the edges of the board cannot be effectively grounded to the box [1]. Often there are multiple ground paths through the ground lugs of coax connectors and the metal mounting pillars.

Why not mount the board flat down on the base of the box? Because it's generally good VHF/UHF/microwave practice to keep the RF and DC components on opposite sides of the board, using feedthrough capacitors to provide DC power to the RF side. If you don't have access to the back of the board, you have to take much more care to keep RF out of the DC wiring.

Much better are the tinplate boxes we can get in Europe, which have removable top and bottom lids. The PC board is cut to size and mounted part-way up the walls, so you can easily get to both sides. The groundplane is soldered all round the walls so that grounding is excellent. RF connectors come straight through the walls and onto the board, with zero lead length.

The boxes are available in a wide range of sizes to suit various kinds of RF modules, and are mostly made by a small German firm called Otto Schubert GmbH. I don't know if these boxes are imported into the USA, but most European VHFers wouldn't use anything else.

[1] If you really have to, you can bolt a large number of bent-over solder lugs to the box, and solder them directly to the groundplane of the board... that will work, but it's better to avoid it.

Automatic Gain/Volume Control. When engaged, it compresses the audio
volume range of signals received so that weak performers and
powerhouses sound nearly the same. This answers your complaint of the
tepid response to otherwise serious change in levels, but is unlikely
to satisfy. Keep the AGC on and observe the S-Meter instead (the
S-Meter is a direct reading of AGC potential in many sets).

Nope, not at all. The white noise generator is perfectly suited -
that is the point of the "noise" in Noise Bridge. It is a source,
nothing else, the remainder of your system already presents the
necessary bridge configuration.

Hi Jason,

And as well it should. This suggests you would feel better with a higher amplitude white noise source. As I said, designing and building a linear amp will test your self challenge. It is not such a difficult first assignment, and neither is it a brush-off.

Perhaps it is the other way round. :-)

You don't seem to be grasping that the part only has to sample at a rate
of at least 2x the *bandwidth* of the desired signal modulation. You don't
have to sample at a multiple of the *frequency* of the transmission. This
sort of sub-Nyquist sampling automatically does a downconversion to
baseband via the well known aliasing phenomena. The only caveat is
that the analog part of the A/D has to be able to work at the transmission
frequency of interest. For the above quoted part, that's an upper limit of
270 MHz. So this part will work fine in a 70 MHz IF.

Perhaps. Or more likely, we speak different languages to describe the same phenomenon.

>
> You don't seem to be grasping that the part only has to sample at a rate
> of at least 2x the *bandwidth* of the desired signal modulation.

Yessir, I grasp that.

You don't
> have to sample at a multiple of the *frequency* of the transmission.

Yessir, I understand that too.

This
> sort of sub-Nyquist sampling automatically does a downconversion to
> baseband via the well known aliasing phenomena.

It is only well known if you've done it before. There is a well-known phenomena that a 6U8 will burn out in a couple of hundred hours if you run the tuner shield up on it, but I doubt todays kids coming out of college would call it "well known" even thought they could run Nyquist loops around me.

The only caveat is
> that the analog part of the A/D has to be able to work at the transmission
> frequency of interest. For the above quoted part, that's an upper limit of
> 270 MHz.

And I went around and around with the data sheet HOPING to find something like that and couldn't find it after an hour of searching. Can you give me a pointer to a page on the data sheet?

So this part will work fine in a 70 MHz IF.

So the original poster assumed a 70 MHz. IF? I never picked up on that. So the drill of downconversion to 70 is still viable? That's fine. Now I come down to some words in the data sheets and appnotes that say something like the sampling will convert the data to baseband. That's a hell of a note to try and understand how a 150 Hz. signal, which can have a possible 8 kHz. error when downconverted to 70 MHz. IF can be found without a lot of scratching around. Understand? The digital stuff appears to require the data in the middle of the passband, and with an analog downconversion I can't promise that without a tremendous amount of stabilization...and even then I don't think I can promise to exactly center the data in the IF

passband.

2029. Re: Digital Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-12 20:33:33 UTC
From: k7itm@aol.com
Message-ID: <3200347.0203121233.2b67a3ab@posting.google.com>
Source record: 45667

Well, you could do it with just a single bit digitization (and therefore lots of noise), but since you can buy digital mixers that work on lots more bits and at reasonably high frequencies, why bother? Analog Devices and TI and some others sell digital downconverter (and upconverter) chips. To digitize the input, have a look at the Analog Devices AD6645, for example. TI has some ADCs that are almost as interesting for digital receiver work. Once you get the signal digitized, you can build the rest of the radio digitally. (We do that where I work...there are some very significant advantages, especially for some customers.) It's quite possible to do the mixing and filtering with an FPGA, too...even the Xilinx Spartan II series could do a respectable job over the HF range if you're careful, and for sure you could do a lot with the Virtex II FPGAs, and I suppose similar things from other vendors. If you don't need video bandwidths, you'd do well to quickly decimate down to slower sample rates, which you could then reasonably handle in a DSP.

Interesting to contemplate: if you set up your ADC for, say, 500mV p-p full scale input at the antenna terminals and it's a 14-bit converter, how small a signal can you detect? What limits the minimum detectable signal?

Cheers,
Tom

> timing, since it would seem that a streetlight malfunctioning wouldn't do this,
> and a driveway light might stay ON for a specific time, but not off! HELP!

You need to pinpoint the noise source with a portable receiver that picks it up
well.
Could be anything from a light dimmer, fish tank heater, touch lamp, outdoor night
light, electronic timer on a household appliance such as a microwave oven, on and
on.
First you need to localize the source so that you
can start shutting off power to the potential sources- homes, business, power
pole, etc.
No exact path can be stated until the source is better localized. You may need to
get utility
company people involved to shut off power to homes etc, to either pinpoint or
eliminate them as the host to the source. You'll be lucky if the source turns out to
be an appliance that you can locate without it.

I was once contacted by utility workers looking for a noise source that was wiping
out most everything including cable TV in a neighborhood. With a portable AM
receiver I soon localized the noise to a power pole that held a large transformer
which fed several homes. I told the utility crew to start unhooking power to the
homes. When they pulled the electric meter on the third home, the noise on my radio
stopped. I had them reattach the meter, and the noise started again. So we went to
the door of that house and pushed the doorbell button. At that instant the noise
stopped, then started again when the button was released. Viola! Arcing doorbell
transformer, was the diagnosis. The utility crew soon had the culprit in hand, and
it was an overheated black glob of tar which had been covered in blown-in attic
insulation. No more radio noise.
You get the drift, it's not an exact procedure, but one leads wherever, a process

of elimination. Noise can move along utility primary lines for miles. Another case I know of
was solved by a cable TV tech who had searched in vain for months for the source, and finally found it by doing a nighttime check of junctions where the HV primary feed split to feed smaller elements of the grid. One of the split-bolt connectors was loose and arcing. Eventually this often burns through the high tension cable and causes a power outage, and utility companies like to fix them first. Any noise that travels for distances instead of being more localized is likely to be traveling on the primary line side of the pole transformer(s).

If you find that the utility company equipment or lines are involved and they balk at helping or move very slowly as they can be prone to do, contact the ARRL for more information on how to proceed. It may be impossible to pinpoint the noise source without their help, as seen above. QST not long ago had a piece noting that FCC had written a utility company when they had failed to clear up radio noise, and it got them moving post haste

Also, ARRL has lots of experience and expertise at RFI solutions and you might find something helpful on their website or via an email to HQ.

Dick W0EX.

Or just drill screw holes every few inches when you mount the board in
the bottom of the chassis. In practice, I usually find that 6-8 around
the periphery of a 4x2 board is fine. The screws, plus the grounding
lugs of any SMA jacks and feedthrough caps you're using, will generally
be enough.

Sounds like a complicated approach to a very simple problem. I haven't even plugged in my grid-dip meter since I built the LC Meter IIB kit from http://www.aade.com. It excels at measuring very small (down to a few nH if you're careful) inductances, so you can tune the circuit right the first time.

Multisection LC filters made with coils tuned by the AADE meter invariably work great with no tweaking.

Correct Gary.

If you designed a 70MHz IF you'd be in great shape.
The signal bandwidth is very low (a few hundred Hertz)
so the only problem is getting the signal down to something
the ADC can handle. I haven't looked at how DDS can go
but I believe 200MHz clocked DDS are readily available.
But you're probably better off with a cheaper DDS and using
the ADC to perform the downconversion.

I don't know what the problem with this link is
http://www.intersil.com/data/an/an9/an9509/an9509.pdf
I grabbed it just before posting and just visited it without
any problems.

As I implied, this is really to familiarize you with what
can be done in the digital domain rather than give you an
exact solution. Having spent the majority of my career as
an analog weenie (and sensing that you are and analog
guy) I thought you might want some background reading
in order to sort thinking of different circuit topologies.

What sort of volumes and product road map are you looking
at? If you only need a low volume of units or can't see the
potential design re-use then maybe embarking down the
DSP path is more trouble than it's worth. But I consider myself
to be more analog than digital and I see many merits with this
approach.

GENERAL ELECTRIC TF4RX02NA Power Transformer

Has four seperate 32 volt @ 4 Amp windings. Connect in series for 128
Volts or +/- 64 Volts Center Tapped. Primary tapped for 109,
115,120,126, and 132 Volts. Potted in military style case with
terminals. Weight: 20 Lbs. Great for 200-300 Watt Solid State Amp.

Picture at:
http://mywebpages.comcast.net/mnowlen/ge-power-trans.jpg

Very Good Condition, Tested and working.
Two available.
$50 each + Shipping
Send zip code for estimate

Oh, I can speak analog tube language too. :-)
I've had to have a foot in both camps in my business,
which uses technologies from the late 1940s all the
way up to the hottest of today's stuff.

I don't necessarily have to know how to design it, but I
do have to know how to troubleshoot and fix it. The best
way to do that is to try to understand the theory behind
the particular technologies. It is a never ending battle to
keep up.

Let me amend that. Understanding the theory may not
always be the *fastest* way to fix today's technologies.
Board level substitution seems to hold that honor. But
I'm old fashioned enough to want to dig deeper than
that.

>passband.

It doesn't have to be exactly centered. But if you expect it won't be, you need to use a sampling rate of at least twice the bandwidth of the 70 MHz IF rather than just twice the bandwidth of the signal modulation. (That's still just low kilohertz.) Then you can numerically tune the digitized result to find the signal and lock onto it. (Digital AFC is really pretty trivial to implement, just use an auto-correlator algorithm to steer it.)

YES!

> 7_"Tuborg dore" ....Tuborg Brewery

What is this in Danish?
The following beers are presently brewed at Tuborg brewery:
Groen (green label); Classic, Roed (red label); Guld (golden label);
Tuborg FF;
Paasekbryg "KylleKylle" (Easter beer); Julebryg (Christmas beer) and
some special
and "light" (yuc!) products. AFAIK Tuborg FF is the most alcohol-strong.
And, they are ALL good modulation-waters, but not made according to
"Reinheitsgebot"

This newsgroup is about building radio-equipment by amateurs.
This is also called homebrewing.
So it has nothing to do with beer.

Chances are high you are not going to find your answers here.
You could try sending an email to the brewers and ask them.
They should know what they brew.

I have been using the S-meter more than my ear, as it takes a low SWR
to make the difference clearly audible. But I don't like the S meter
on my Kenwood TS-430S. It resembes a shrunken version of the
speedometers of some 1960s and 1970s GM vehicles like the one on this
1969 Cadillac
(http://kevingilligan.tripod.com/sitebuildercontent/sitebuilderpictures/inst.jpg).
Imagine that the Cadillac speedometer is shrunk so that it is just 1
inch in diameter. Then imagine that the marks for x5 mph (05, 15, 25,
35, etc.) are taken out. You'd have difficulty telling whether you
were driving 53 or 57 mph. This should show you why I don't like the
S meter on my rig. S5 to S9 is the middle of my S meter, and the
marks are so close together and make it difficult to notice subtle
changes. The area beyond S9 is difficult to read, because each
marking represents a 20 dB change instead of the 6 dB typical for the
S1 to S9 area.

With the 20 dB attenuator on, I usually find that the noise bridge
gives me an S9 reading for a mismatch and an S5 to S7 reading for a
match. Because the bandwidth is so narrow on the lower bands, I
sometimes overshoot because I miss that QUICK null. If I had to rely
on the S meter, I'd rather have a mismatch correspond to S5 and a
match correspond to S1 to S3, as the meter is easier to read in this
region. Also, the audible noise level difference would be more
noticeable.
>
> And as well it should. This suggests you would feel better with a
> higher amplitude white noise source. As I said, designing and
> building a linear amp will test your self challenge. It is not such a
> difficult first assignment, and neither is it a brush-off.
>
OK, I see what you are getting at. I want an extra amplifier built-in
to strengthen the noise source. The reflected component of the
received signal resulting from the noise bridge would dwarf the low

band spikes I have been complaining about. I'd also want to put in an attenuator to avoid overloading the receiver. Since I'm stuck with my lame S meter (as I don't want to add the complexity of a frequency control to the noise bridge), I would also want to make the amount of amplification and attenuation adjustable. Thus, I can make S5 the mismatch noise level and S1 the match noise level instead of S9 and S5.

To distinguish between an SWR of 10 and an SWR of 100, I'll probably need some type of differential amplifier in the circuit. I have noticed from the equations that the reflected voltage for an SWR of 100 is not much higher than that associated with an SWR of 10. So I think I can use a toggle switch to activate such a differential amplifier. This will allow me to easily see that I'm getting closer to a match on 80m, even if my SWR is still 5-10 or more.

By the way, Richard, thanks for your comments. I have a better idea now of just how a noise bridge works.

Yes. Jiggle the range selector knob and see if the frequency display comes back from 0. Mine does this, as does a friends' unit. In his case, he has to actually hold the knob slightly turned to get it to function. As soon as he lets it go, the display (and probably the oscillator) goes to 0 again.

Let me know if MFJ is willing to fix it. I haven't bothered.

Jason, my suggestion would be to connect a sensitive AC voltmeter across the speaker output of the TS-430 and do the following:

(1) Crank the RF Gain control completely counterclockwise (ie: full off)

(2) Crank the AF Gain control completely clockwise (ie: full on)

(3) Turn on the Noise Bridge and adjust the AC voltmeter sensitivity and RF Gain until you have full-scale meter deflection and a comfortable listening level.

(4) Tune for a null. A 6 dB reduction in bridge output will now correspond to a reduction in meter deflection to half scale. If, as you approach the null, you find you need more sensitivity, adjust the RF Gain upward so that the meter is once again at full scale and continue.

(5) Ignore the S-meter entirely (of course).

If I want to connect an rf amplifier circuit, such as a MAR-X amplifier to the input of a Spectrum Analyzer or Oscilloscope, which connector would I use? I could use chasis mount BNC connector, but is this connector the right connector for a 1GHZ amplifier? Is VCR cable connector a good connector? Does using an adapter to convert fom one type of connector to BCN connector change the usable frequecy?

And this link came through just fine (I let it sit twice for ten minutes yesterday and it just sat there blank with "done" in the to-do box). I got the general idea from this data sheet, but even this reference presumes a universe of knowledge I don't have.

I'm really not arguing with you guys, at least not Steve and Gary. However, I'm somewhat baffled by acronyms that you all take for granted and I'm just learning. To put it in some perspective, consider the computer engineer that wants to know something about constructing an antenna. To send him to references that consider the triple integral of the phase front when all he wanted to know was how to whack up a dipole isn't helpful. The AN9509 reference below is great.

Now, the final question and perhaps we can all get out of this thread alive...are there other references such as the 9509 below that take an analog beginner gently by the hand into the wonderful world of digital doofusing without all the ocean of detail? I mean, it is fine and wonderful to learn how to use a micrometer, but if you haven't been exposed to a yardstick, it is a lesson too early. Perhaps the ARRL Handbook of the digital world?

Hi Jason,

I see no reason to add or use an attenuator, there is absolutely no problem with overloading the front end. Your source may effectively provide a fraction of a Watt in power, but the band pass filters of your TS-430s (same one of two HF rigs I have, the other is a Drake TR-7) easily pushes down the amount of power applied to the first mixer to a level of microWatts. In fact, it would be a paradox to build an amp for the white noise source and then attenuate it.

The simple solution would be to tap off that S-Meter voltage and feed it to a VCO in the audio range that in turn drives a separate speaker (or mix it back into the audio chain through a special switch). This is a very cheap design that could be accomplished with the venerable 555 timer chip, or with the already mentioned VCO's which would interface easier - perhaps.

This would give you a variable tone whose frequency is driven by the S-Meter level. By Adjusting the top end frequency and bottom end frequencies of the VCO to match full scale deflection and no deflection, you will find that your ear does far better in resolving differences that escape your notice by viewing any size meter.

As for your complaint that you sometimes miss the null because it is so sharp, you are arguing the opposite. When I use my TS-430 for bridge applications the nulls easily plunge 100dB; what you describe seems to be a tepid 30 or 40dB at best (if then). This is not your fault, it simply an illustration of balance, bandwidth and isolation (which you may be suffering from the lack of). If I were to use my own idea of the whistling S-Meter, the 100dB notch would sound like a low thump in a warble, as I traversed it. If I inverted the voltage to frequency conversion, it would be a quick high chirp, or click, in a field of rumbling. The occurence of either of these two indicators would be enough to cause you to tune back and peak the response. For anyone who has tuned SSB, it is more than obvious how much difference several 10's of Hertz can make. The ear is a very good discriminator. With a full scale equivalent at 1000Hz, this would be the log equivalent of less than 5% resolution, something entirely lost in a 1 inch meter.

I get both EDN and Electronic Design, and I've been both an author and a seminar host for RF Design. However, for whatever reason, RF Design stopped coming about a year ago and nothing I write to them seems to turn the faucet back on. Go figure.

And, of course, all that "digital crap" I never thought I'd want to dick around with has long since been consigned to the recycle pile...if I kept every article I thought I'd use some day I'd have to rent the Taj Mahal to file it, employ two librarians to keep track of it, and if I started to read everything of interest in our field today, by next year this time I'd be two years behind {;-)

A good-quality BNC connector is fine at 1 GHz.

> Is VCR cable connector a good connector?

No. CATV cable is the wrong impedance, doesn't bend well, and generally
has low overall shielding quality (read: the minimum necessary to
accomplish its intended purpose). (Obviously, the RCA-jack cables used
with VCRs are right out at 1 GHz!)

> Does using an
> adapter to convert fom one type of connector to BNC connector
> change the usable frequecy?

It can, if the adapter is of inferior RF quality. With BNC hardware in
particular, you have to watch out for LAN-grade components that were
never meant to pass signals greater than 10-20 MHz. There are some
truly terrible BNC adapters and cables out there that could lose upwards
of 10 dB or more at 1 GHz.

For homebrewing with MMICs, I use SMA jacks and cabling. Their physical
size and RF characteristics are much better suited for use with
GHz-range components than BNC. Go surf around on eBay, and you'll find
all the interconnects and cables you need.

Bnc connectors are not good at 1ghz. Type N is much better. Tnc is ok.
Look at some of the better test equipment like HP or Motorola. Most
all have type N when 1 ghz is involved.

Adapters are bad at frequencies well below 1ghz. This is assuming that
you are concerned with very low vswr.

I can explain this parodox. The amplifier would ensure that the
reflected voltage is strong enough that those darned noise spikes
don't foil my efforts to find the null. The attenuation would be
adjustable. I'd like the noise level corresponding to a mismatch to
be S5 instead of S9. The S1 to S5 part of the S meter is easier to
read than the S5 to S9 part.

OK, I guess I didn't express myself right when I said I missed the
null because it was so sharp. Actually, the null was VERY narrow.
When I tune on 80m, it's easy to miss the null. For my DK3
Screwdriver antenna, the SWR doesn't decline all the way to 1.0 on
80m. I can only get it down to 3-5, and the S meter doesn't move that
much to get here from high SWR values.

Hi Jim,

Try this link

http://www.dspguide.com/

this has a free electronic copy of "The Scientists and Engineer's Guide
to Digital Signal Processing".

I've got a free paperback copy that ADI was giving away a few months
ago. A pretty good guide for the price ;-) Maybe they still have some.

ADI's softcopy is here
http://www.analog.com/technology/dsp/training/materials/dsp_book_index.html

There is a very good course called "DSP without Tears" if you can get your
company to foot the bill...

http://www.zdt.com/shock/dsp1.htm

You'll probably like that one because the guy who created the
course was totally pissed off with academics who deliberately
made the subject look complicated in order to pump up their
self-esteem and make it look hard. I haven't taken the course
but I hear he's good.

I came from an analog background and on one hand there is
the learning curve with thinking digitally etc. But on the flip side
you will find that there are people from the digital/software side
who are learning this stuff and getting totally hung up on what
the objective is (which is totally analogous to the old-fangled
analog). You will have a big leg up on them if you know the
different filter topologies and uses etc. Also, you will have
a better appreciation of what the analog equivalent would cost.

Look at Chapter 21 for a comparison of analog/digital
filters.

http://www.dspguide.com/ch21.htm

From an analog background I liked the FIR filter.
It is easy to understand, inherently stable and because
it has zero phase distortion it has big leg up on most analog
filters. The downside is that it uses alot of gates (which
get cheaper every year, unlike op amps and quality
discretes). So the digital guys often turn to IIR filters to get
similar performance with fewer gates. The downside?

Hey, this is starting to look analog. Those damn IIR filters
can oscillate and/or introduce phase distortion. Your back
to the same old problems of analog.

Hope you enjoy the reading. Now go whack that dipole...

I have not tried it, but I understand that pulsing the power to the
noise source a couple times a second makes the bridge noise more readily
distinguishable from the normal band background noise. This aids in
tuning for a better null, especially in the presence of band noise.

Source record: 45613

I am looking at my ARRL handbook (1999, chapter 15, page 15, which shows how a diode ring mixer switches. It is normally a three port device, RF input, LO input, and IF output. The diagram shows the IF output off the center tap of the secondary side of the RF input.

Since the LO is not driving the ring directly, it looks like the affect of the switching diodes is to reverse the polarity of the input RF signal to the IF at the LO rate. This is where the switching action comes from.

One way to do this with no LO connection, is to set the RF secondary center tap to RF ground (bypass with a 0.1 uf cap) and apply the 1.5v or 2.5v DC switch bias at this point. A simple resistive divider works well for the bias for my detectors. I use two 2.2K resistors and a 47 uf cap and a 0.1 uf cap at the 1/2 voltage junction.

Take the two secondary transformer ends and feed them to the 2:1 mux chip. The common end of the mux chip (the "1" side) should be AC coupled to the IF stage, while the "2" sides of the mux each connect to one end of the RF input transformer.

The LO feeding the select line of this single 2:1 mux chip will then reverse the phase of the incoming RF to the IF port with each half cycle of the LO, giving the proper mixing action.

These devices will likely be available from Digikey, quantity 1 sometime soon. I see that Digikey has them in their database, but have none in stock. If you really had to, you could use the TI 74CBT3253 or 74CBTLV3253 part that is in stock (dual 1 of 4) to get the "1 of 2" action you need.

Hi Guys;
I have these panel meters that I had bought once for my pal W7ASW, here on long island, A long time Homebrewer. Unfortunetly he shortly therafter became a SK.
So I have these 5 sets(10 total) Made in England Panel meters.
They are high quality and have been tested at 5vdc for full scale as the meter scale says. They were made to read temperature so you'll need to shunt accordingly.
The internal shunt is a 5K ohm resistor with plently of room to replace it, easily.
The meter measures 4"w x 3-1/2"h, with 3/8" thick from panel face. looks like it needs a 2.5" hole in the panel. These are used but just need a bit-o-cleaning & they'll be really nice.
The Scale can be easily removed with a few screws from the front, scanned into your 'puter & remarked/printed out & then pasted over the original aluminum base plate of the scale.
Here are some pics>>
http://www.baltimorepress.com/~wa2rqy/panelmeter1.jpg
http://www.baltimorepress.com/~wa2rqy/panelmeter2.jpg
http://www.baltimorepress.com/~wa2rqy/panelmeter3.jpg
Price is $15 per set shipped.

I have made the following experiment: I took a PC monitor and switched it on. Then I took a new ordinary colour negative film. I went into a dark room and pulled out one half of it. The first half remained in its tin can, and I put the second half into its black plastic box. So the first half of the negative was protected by a tin box, and the second half was protected from light by a strong black plastic box. Then I stuck both the halves onto the middle of the monitor screen with some adhesive tape, and left it there for four hours. After that time I had both the halves developed. The first half from the tin box was completely transperent, i.e. unexposed, while the second one from the plastic box was completely black, i.e. exposed. Exposed to what? Obviously X-rays!!! I repeated this experiment with several other types of monitors, but the result was always the same.

Factories never give any data of the X-radiation of their screens. How strong is it? Some people sit by the screen for 8 hours a day, 250 workdays a year - year after year. How dangerous is it? Does anyone know something more about it? Why don't factories pulbish that radiation in radiation units? Any comments?

Ihave two Analog devices AD797 low noise, low distortion amplifiers I am going to use as post mixer amps in a quadrature receiver for SSB. Looking at the spec for noise, it is somewhere between 0.9 and 1.2 nV/sqrt Hz. My noise measuring equipment verified this. However, this amplifier is still not quiet enough, as I have built a circuit which IS, using a parallel pair of 2n 3904 transistors which give a NF of about 2dB. Is there any way of stitching together a desceete amplifier and the AD797 to have a combination low noise amp with high dynamic range? i suspect not somehow!
Thanks from Rod VK6KRG

Hi dr OMs,

Thanks for reading this mail. It is about the following. As a teacher i want to do an experiment on the Doppler-effect. For that purpose i would like to make a very little circuit (based on a NE555?) which generates a sinuswave that is heard through a little loudspeaker and that can be built in in a little ping-pong ball. By moving or throwing that into the classroom, i want to measure the Doppler effect.
As a ham, i am sure that someone has a scheme of a CW practise generator that does want i need !
So if you can help me, pls let me know. My students and myself are gratefull for any tip !

Message-ID: <a6r2d6$1ld$1@woodrow.ucdavis.edu>
Source record: 45624

In generic common circuits, the input impedance is high and the output would be moderate to low. It all has to do with the way it's placed into a circuit. Parts around it, change the impedances.

The mpf-102 is/was used extensively in hf and vhf circuits, I'm sure many examples can be found in ARRL Handbooks.

cheers
skipp

Well, yes, I think it can be done. For high dynamic range, you want low distortion and a reasonably high power supply voltage...though in fact, I guess it's doubtful you'd need a clipping level that's terribly high since your mixers will be limited by their compression point if not their distortion below that. You might consider a bootstrapped cascode input stage...you didn't mention what configuration you're using right now. With appropriate feedback, the bootstrapped cascode can be quite linear...distortion products similar to what you'll see with an AD797 or OPA627. You could include an AD797 if you want, though you can also just do the whole preamp stage discrete. (You may find some interesting ideas if you do a search for "moving coil preamp" as related to phono preamps. They deal with trying to get low noise with a low-impedance source, and a wide dynamic range--especially before the equalization.)

So...what configuration do you have now, and what are its shortcomings?

By the way, there was a discussion about a particularly low-noise amplifier on sci.electronics.design a few months ago. I wish I could provide a better pointer to it, but I'd have to go do a search to find it.

Cheers,
Tom

Hi Roy,
That would be a comforting alternative. However, I do not know if those electrons could penetrate through 6 milimeters of glass, 2 centimeters of air (on average, without any visible effect?) and 1 milimeter of plastic? Is 30 kV enough for that? I am afraid they are X-rays.

BTW:I am afraid that the cumulative effects of time are being neglected when using monitors. The damaging effects of radiation depend on the level of radiation multiplied by the time a person is exposed. If those are really X-rays, a time limit for watching at near distance should be also stated on the CRT.

I hate to see this sort of misinformation passed along. BNC connectors are very good up to at least 4 GHz, and you'll find BNC attenuators rated to at least 12. (Between 4 and 12 their disadvantage is primarily signal leakage, which might or might not cause a problem.) It would be fine for your application. With the exception of "UHF" connectors (PL-259/SO-239 types), quality adapters won't materially degrade signals in the 1 GHz range.

The most degradation you'll enounter is in trying to get the signal from your amplifier to the connector. Just about any way you do it, you'll pick up some series inductance which might reduce the output signal amplitude. The best way is to run a microstrip line directly to the center pin of the connector, and mount the connector's shell in direct contact with the ground plane. A good match (usually meaning lower series inductance) is easier to do with smaller connectors, such as the SMA. But if you can get the signal to the connector, a BNC will work as well at 1 GHz.

People doing precision metrology have much more demanding requirements, so would probably avoid BNC connectors because of small inconsistencies from one mating to another. But for nearly any other purpose, they're fine. And they're inexpensive, easy to get, and adapters, attenuators, and other accessories are common and relatively inexpensive. I use them exclusively unless I have a real need for a smaller connector, in which case I use SMA.

Right, but there's BNC and then there's BNC. My guess is that he based
his post on empirical observations made with LAN-grade BNC hardware.
There is so much BNC hardware out there that isn't fit for use above the
2-meter band it's not even funny. The only way to be sure about a
given BNC part (at least as far as I could ever tell) is to check it on
a tracking generator or VNA.

On the other hand, SMA hardware is pretty much guaranteed to be good to
a few GHz, probably because it was never commoditized and cost-reduced
by the PC industry the way the BNC standard was back in the 10Base2
days. And as you say, it's much easier to make short, low-loss
connections by hand with the smaller SMA connectors. N-type connectors
are obviously even worse than BNC in this respect, and shouldn't be
considered for homebrewing except in panel-mount applications.

SMA hardware and cabling is so darned cheap and plentiful these days
thanks to eBay that it just doesn't make sense to use anything else,
IMHO.

2088. Re: simple connector question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-15 02:40:51 UTC
From: gaschafer@attbi.com
Message-ID: <3c915764.43090602@netnews.attbi.com>
Source record: 45627

It is not misinformation. A bnc connector does not have a flat
impedance response through 1ghz. Yes they are fine for a lot of
applications including 1ghz operation. Even a pl259 will work at
1ghz.
But if you are concerned with flat response over the entire range as I
pointed out a type N connector is supperior.
Measure the vswr on some adaptors sometime, even at frequencies of 450
mhz. They are anything but flat. will they work for a lot of
applications, sure. But if you want very flat response for something
like a spectrum analyzer, like he asked about, a type N is the better
connector.

I use bnc connectors and adaptors much of the time too. They are handy
and easy to find attenuators for etc. But look at any good signal
generator that operates at 1 ghz. It will have a type N connector. The
reason,, Because it has a flater response at 1 ghz.

If it is for general use and you are not concerned with any serious
measurements at 1ghz then bnc is fine.

|Bnc connectors are not good at 1ghz.

BS.

|Type N is much better.

Type N are more robust and more repeatable because they screw on.

| Tnc is ok.

TNC are better than "ok". I know of a military program where a TNC is handling >300W at 10 GHz.

|Look at some of the better test equipment like HP or Motorola. Most
|all have type N when 1 ghz is involved.

That is because they are rugged and can stand many, many connect/disconnect cycles.

|
|Adapters are bad at frequencies well below 1ghz. This is assuming that
|you are concerned with very low vswr.

If you are in a metrology lab, that may be true. But "connectors" are bad if you are concerned with very low VSWR, although beadless 7mm connectors and airline are great, but not too practical.

This is the sort of discussion that could go on without end. But I should point out that there are several series of BNC connectors, some better than another when very flat SWR is an issue. (It isn't, in the application being asked about.) As I recall from the distant past, the UG-88E was a constant impedance connector, while some of the others of that series weren't. It's not a trivial job to measure the SWR through a connector itself. (That is, unless you're using a 75 ohm BNC in a 50 ohm system.) A poor apparent SWR is more likely due to a poorly installed connector than to the impedance discontinuity through the connector itself. I have in front of me a 1991 HP Microwave Test Accessories Catalog which shows the SWR of general purpose BNC connectors to be 1.3 up to 4 GHz. This is acceptable for nearly any general purpose application, and for most laboratory applications.

There's no doubt that any screw type connector, including TNC, is more consistent than any bayonet. I just maintain that this level of consistency is seldom required unless precision measurements are being made. I'd expect to find a threaded connector on any good signal generator both because of the improved consistency and also lower signal leakage. (Not because it has "flatter response".)

People like to sort things into binary groups, "good" and "bad". You'll see it in the discussions of antennas and nearly anything else. But "good" for one application is "bad" for another, and stating without qualification that BNC connectors are "no good" for use at 1 GHz is simply wrong for most applications.

At this point I'll retire from this thread. There's plenty of good information easily obtainable from the web for anyone seriously interested in this topic.

Bill
It depends on the configuration of the mixer and which port you are
referring to.
In an amp circuit with a common source configuration the input impedance
would be high and would normally be set by a resistor to ground.
In a common gate (grounded gate) configuration the input impedance will
depend on drain current and FET gm. In fact this is a good circuit where you
want a wideband predictable load (eg post mixer amp).
In a mixer I presume both situations will apply as you will probably be
applying RF to the gate and LO to the source. (no doubt there will be more
learned responses to enlighten us)
You could enter the circuit into a simulation package and see what you get
(I dont know how good the simulation is in this situation)

Not exactly. It proves that there is an unknown amount of radiation near the monitor screen. The next logical question is: "How strong are they?" The answer should be in adequate measuring units. The general radiation in the room is musch lower. I let a piece of the same film in a black box in my drawer for a month, then I developed it. It was completely transperent, i.e. unexposed. Conclusion: There is a substantial measurable amount of radiation near the monitor screen.

Hi!
Your smart experiment indicates that the radiation could be stronger than I suspected. I did not try to find out the minimum time needed to darken the film. You say 30 seconds. The next time I will take that time. In fact the TV cathode ray tube is technically very similar to the X-ray tube. There is a strong beam of electrons from the cathode hitting a highly positive metal anode. Secondary products are then beaten out, i.e. the X-rays. The screen is conductive and could stand for the metal anode. You have proved that a monitor can be used as an improvised X-ray machine.

Here in Europe the X-ray machine is called 'Roendgen' after its inventor Wilhelm Roendgen, who has also discovered the X-rays (Nobel prize 1901). The measuring unit is 1 Rg (roendgen). When the impact of X-rays on people is considered, the time of exposure is essential, so the measuring unit is Rg/h (roendgen-hours). The other day I looked into a Medical school textbook for a "roendgenologist". Under "professional risks" they say: possible sterilization caused by X-rays. Those people in hospitals are protected by lead walls and stand at least 10 feet away. Our children sit 1 or 2 feet from their monitors. Am I a panicker?

Now, what I am trying to find out in this news group is the million-dollar question: "Our childern sit in front of their computers for hundreds of hours. Could it happen that they become sterilized, or - when they grow up - that they get monster and reterded children like those we can see around Chernobil today?" Exact numbers are needed; funny anegdotes do not help here. Judging by some answers I have touched a wasp nest. I am aware that producing monitors is a multi-billion dolar business today. Who should I believe to?
Greetings.

Hello all,

I like to come to forums where the interest is in radio. I have just made my first website and have all the information one needs in order to make a truly remarkable circuit. I call it the "Radio Shack Special".

It is really a super-regenerative receiver that I had doctored up so much (by taken off component after component) that all if left is 12 components in the receiver itself. The sensitivity, selectivitiy and great audio output is truly an understatement.

You have to go to the site and see for yourself. I have laid down ALL the criteria for one to get it up and running.

I quess it is these simple projects that just become so fascinating.

Usually, with FM, all sorts of detectors, discrimators..etc. you need to have.

This little gem is shining so bright...I listen to it every night before I go to bed....just for the fact that it is picking up FM.....and sensitivity!

Pedro was the first person to try it.....he started the journey...and now has finished it and added fine touches to the outer jacket as to make it look so professional...

If you are interested in this.....you need to go to my website and take a look at the amazing "Radio Shack Special". I call it that because all of the components may be purchased there....except for the tuning capacitor.

...I do want to thank each and every one for the time given.

...your friend, Patrick

2095. Want an amazing week-end project to make....

Does anybody have a cross reference list for the older Toko coil numbers, K1731 and 4921 in particular?

I tried to access the Bonex online catalogue, but it keeps giving me a virus alert (w32nimda). You don't want to go there!

Is there another comprehensive Toko catalogue somewhere?

Thanks
Dave m0cem

That would have been the thread I started. Go to Google - Groups and
search for "Low noise amplifier design". The subject was a 100k-100MHz
amplifier with 300pV/rtHz input-referred noise and a 50 Ohm input
impedance.

There are rules established for this.
The tag on the back of my monitor states that it complies with DHHS
rules 21 CFR subchapter J.
So the factories do not have to publish these numbers because they have
to be lower that the values set in the rules.
These rules obviously exist for your health and safety.

If you are scared of radiation then I would suggest you dig a very deep
bunker in the ground, plate the walls with 15 centimeters of lead. Step
inside and close the door.
But do not come complain about lead-poissioning.

Radiation is a naturally occuring phenomenon and we can handle some
without a problem, however we need to make sure the amount remains
within limits, and that is why we have the rules.

Just a little anecdote about radiation.
Not so far from here a storage complex for low-grade nuclear waste has
been build.
The people living in the direct neigborhood were very worried. So an
engineer volunteered to take some people on a tour of the facility with

a geiger-counter. Turns out the radiationlevels where higher at the entrance-gate then they were inside the complex. This ofcourse puzzled the engineer.
So in his free time the same engineer and some neighbours went out and tried to determine the cause of the radiation. It turned out to be a natual occurance of radioactive radon-gas.

You see people are too often scared because they do not know what they are dealing with, my advise to people who ask themselves this kind of questions would be to go and find somebody who knows and certainly never immediatly believe what the mainstream-media write about it. Because, trust me, they do not have a clue.

Radio Shack sells a 1-piece speaker/oscillator that fits in a 1
cm. cube and can be driven with 3VDC or so. It costs under $10,
and puts out a pretty constant 3KHz or so; driving voltage does
not appear to change the frequency as long as it's over the
threshold required to get the thing to oscillate.

Your local consumer electronics parts houses may have something
of the sort.

Hi Mike !

Thanks for the tip ! It should really be that what i am looking for ... unfortunately i live in Belgium and Radio Shack has closed all his stores some years ago ... Maybe i can find the scheme so that i can assemble it myself.

Yeah Jim... You are supposed to be arguing about who has been on RAH longer, or who brought the HOMEBREW beer to Pville, or in a pee contest over your degrees, etc... You are not supposed to be contaminating the group with postings about actually building something...

BTW, I have been in and out lately so I'm a bit behind on this one... SO, gimme a brief description of the stages and general idea how you you will measure the amplitude depth on each tone... Gonna use a catv bipolar for the rf stage? etc..

2106. QUESTIONS on the noise generator in the ARRL's noise bridge circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-15 17:03:46 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203150903.3ebf48e5@posting.google.com>
Source record: 45644
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have some questions regarding the noise generator for the noise bridge circuit on page 27-25 in _The ARRL Antenna Book_ (layout at http://www.arrl.org/notes/hbk-templates/rxbridge.pdf). As you can see, the chief component of this is the NE555P chip (http://focus.ti.com/docs/prod/folders/print/ne555.html, http://www-s.ti.com/sc/ds/ne555.pdf).

The book says that this noise generator produces a 50% duty-cycle 1000-Hz square wave signal. This signal is applied to the cathode of the Zener diode and then sent on to the amplifier. So the NE555P chip produces the white noise and the Zener diode seems to be the mechanism on which this white noise is placed on a broadband RF carrier. I noticed that the port 4 (RESET) continuously receives 9V, presumably to ensure that the chip constantly resets and doesn't get stuck in one state (as some variation is needed to produce the pulses). Port 8, of course, needs 9V in order to keep the digital elements (flip-flop, BJT, and logic gates) running. Port 3, of course, is the output.

I wish the book described this circuit in more detail. My questions:
1. What does the 6800-ohm resistor between the VCC port and the DISCH port do? Does this influence the frequency of the white noise generator?
2. What is the purpose of the 6800 ohm resistor and two 1N914 diodes between the TRIG and DISCH ports? My guess is that it is part of a feedback network used to generate the square wave.
3. What is the purpose of the 1800 ohm resistor between port 3 and the D3 Zener diode?
4. How exactly does the D3 Zener diode modulate the output of the noise generator onto a broad range of RF frequencies?

YOu need to read up on how the 555 IC works. The two 6800 resistors along with the capacitor determin the frequency the circuit oscillates. One resistor is the on time and the other is the off time. The 555 will not give an exect square wave output of equal on and off times. The diodes are placed in the circuit to help make the times nearly the same.

The 1800 resistor limits the current to the zener diode which is acting as a noise generator and also isolates the circuit so the biggest part of the noise will go to the output to the transistor amplifiers and not be shunt to the power source. The zener does not modulate the noise output but it is the noise generator. The 555 timer output is turning the zener noise off and on at around a 1000 hz rate.

Dear Ian!

Your answer is most informative and welcome. That is the answer I was looking for. Thank you for your time and effort to write it. Of course I am a worried parent - my son works as a professional computer graphics animator at the local TV station - surrounded by six powerful computers with huge colour monitors - for 8 hours every day and in a 10 x 10 foot room. Now I feel better. Thanks.

I believe you have it the wrong way round..
The Diode generates the 'noise' and the 555 interrupts the 'noise'.
In reality, the 555 switches the power to the noise generating diode,
generating a signal that can be crudely called Amplitude Modulation
(I would call it a simple PCM without the 'code').
A carrier pulsed on a 1:1 on/off state will appear to be modulated if
it happens at an audible rate.
In switching at this 'rapid rate' harmonics will be generated..and
accuracy will be diminished.
I could be wrong.. I usually am

I did the same once with a color tv. Only needed about 30 secs. I had
a sheet of photo paper inside the front cover of a magazxine. I put my
hand over it. When I developed it, I had a fuxxy xray of my hand and
where my hand wasn't, the ink in the printed blocked enough so it was
a revese picture of the cover with my xrayed hand super imposed.
This was a 1970's color tv.

Hi Jason,

Your best and cheapest source of information about the characteristics
and application of the 555 come from the manufacturer. Motorola's old
handbooks and application notes are superb in this regard and go to
considerable extent for this chip alone.

The 555 establishes the dominant low frequency characteristic as the pulse edges are the compelling feature of harmonic generation. The Zener is the source of MF/HF/VHF noise. If you want to focus on anything, it should be the Zener. As an experiment, you could remove the Zener and couple this pulse through a transformer (about 1:10 or greater) and fire an NE-2 bulb which will be harmonic rich too (gas tubes are very noisy). I don't imagine that it would show any greater noise field however, unless you contrive to dump more power through the tube (or Zener for that matter, in that regard, try biasing it into greater or less conduction).

Keep in mind that the purpose of a white noise generator is to spread the AVAILABLE power EVENLY across the spectrum. The same power applied to any noise generator can only replicate this characteristic (unless the substitute is not equally suited for the purpose of noise generation). Again, focus on both the power applied, and the noise generation mechanism (there are many candidates). A mercury wetted reed relay feeding an Ampere to a one ohm resistor will overload you with harmonics of the reed's drive frequency. The principle benefit of such a suggestion lies in the exceptionally fast rise and fall time (sub nanosecond) and power handling capability. I won't go into the environmental risk and the possibility of this device becoming a controlled substance by the way.

The 555 produces a chopped DC supply to the zener (actually, avalanche)
diode. The diode produces the broadband RF noise.

For information on how the 555 works, take a look at a
practically-oriented electronics text such as 'The Art of Electronics'
by Horowitz and Hill.

>3. What is the purpose of the 1800 ohm resistor between port 3 and

To set the current through the diode, and also to act as an RF 'choke'.

>4. How exactly does the D3 Zener diode modulate the output of the
>noise generator onto a broad range of RF frequencies?
>
D3 *is* the broadband noise generator.

Yes, he did post about it a while back, and I picked it apart here and
in rec.radio.shortwave Obviously, he just forgot to post the URL 9at
least he's dropped the "email me for details", and in his other post
made at the same time as this one, he did include the URL,
http://braincambre500.freeservers.com

He even has a comment about the "design" from Charles Kitchin, whose
work this "special" is derived from, on the site. It's chopped off,
but it sure looks like Charles isn't all that impressed.

Like I said when the guy posted a while back, there is nothing unique
about this design. And by stripping out the "extra parts", it just
reverts to the sort of circuit you see by the bucketfuls over the years.
The fact that it does give good performance is a reflection of
the technique of superregen, not this specific design. By making
the design more complicated, as Charles Kitchin has done, you actually
get improvements.

db(atten) = 10 log (Pin/Pout)
db(atten) = 10 log (800mW/200mW) = 10 log 4 = 6dB attenuation

regards,
Mark.

The QTH group isn't too bad, but there is probably more CW info on QRP-L,
although if what you really want is just CW, the signal/noise ratio would be
pretty bad there.

I'm sort of squirrelly about the Yahoo groups, I get plenty enough spam, so
I can't comment on their content.

I would like to build a modified version of the SWR noise bridge shown on page 27-25 of _The ARRL Antenna Book_. The schematic is available at http://www.qsl.net/wq1rp/noisebrg.htm, as the New England QRP group sells a kit.

One of the modifications I would like to make is an extra RF amplifier. More forward power means more reflected power given the same SWR. I want the noise from the noise bridge to be stronger relative to RF picked up by the antenna, because noise spikes or strong signals can foil my attempts to minimize the SWR on 80m and 40m.

At the same time, I would like this extra power to be OPTIONAL so that I don't have to waste the battery. This requires use of a switch.

However, I understand that the variable resistor and capacitor in the original design of this circuit are sources of stray capacitance and inductance. Would using a switch have a similar effect? If so, what would it take to minimize this?

Hi Jason,

There are many issues with this design, one of which is that it is a fixed bridge and may not meet your expectations (the bridge is balanced against the 100 Ohm resistor on the "unknown" port). In other words, the layout is not conducive to balancing the arms of the bridge, but rather seeking the balance of what is applied and changing it. It is presumed that the Hi-Z of the "unknown" presents only the 100 Ohm to balance against R1 and C1 is adjusted to compensate for stray capacitance at the "unknown" port (you will never eliminate strays, it is more meaningful to know how to balance them).

Your question about the switch should be immaterial to the operation of the bridge as the source sees only the receiver as a load with a balanced load of R1-C1 and "unknown" in parallel. That is, stray capacitance to ground may affect HF/VHF performance (sensitivity) but not accuracy of balance aside from severe imbalances due to stray coupling to ground or in the coupling from source to R1-C1 and the "unknown" port. In this last regard, the principal culprit is found in the bridge's transformer and the very near connections shown by the layout (not a good idea). This is a rather fine point, one where accuracy is jeopardized, but the authors treat this project as a low accuracy (but adequate) device. Don't project problems of low noise amplitude until you build it.

It is a good begining, but the authors' conjecture that phase angle can be found is dreaming in technicolor with surround sound.

Anyone got any tricks up their sleeves to allow NBFM (12 kHz channel spacing) demodulation directly at a 21.4 MHz IF, without the usual downconversion to 455 kHz?

I'm looking to use the Philips SA604A FM IF subsystem chip, and I have a good assortment of 21.4 MHz monolithic crystal filters to play with. It would be nice if one of those filters could be pressed into service as the equivalent of a very-high-Q quadrature tank circuit. The required quadrature Q for NBFM recovery at 21.4 MHz is on the order of 1000, too high for the usual LC circuit.

How about useing a 21.4 xtal in place of the LC tank. ISTR seeing this
used at 10.7 on the CA3089.

2135. Re: Radiation from monitors

Newsgroup: rec.radio.amateur.homebrew

From: cwsouth <cwsouth@telusplanet.net>
Message-ID: <01c1ccce$b2919860$3a37b8a1@cwsouth>
Source record: 45573

Hi All:
Let us put some of this into perspective, and avoid fears born out of ignorance.
Prudence and caution are always useful when based on verifiable facts.

I have been an industrial radiographer and design radiation measurement equipment for some years.
I have had a my lifetime dosage plus and I am still here.

The radiation from the monitor is minor in comparison with an airline flight at 30,000 ft.

If you live in a brick house, your radiation dose is much higher than a wood house.
Radon from igneous rocks can cause major health hazards.

The naturally radioactive elements potassium, uranium and thorium have energies as high as 1.4 Mev or about 47 times the level of the maximum output of a CRT at maximum brightness.

Film triggers, due to radiation, at various levels due to the density cross section of the film being able to absorb a passing x-ray. Colour film's silver halide salts are not efficient at absorbing X-ray radiation.
Film Dosimeters have been dropped in favour of TLD (Thermo Luminescent Dosimeters) in Canada.

A Geiger Mueller tube will only pick up 1 % of the radiation emitted. And it must be tuned to the energy of the radiation for any reading to be useful. Expensive Scintillation radiation counters are only 7 % efficient.

Industrial x-ray film triggers at certain levels of energy (kilo electron volts or Mega electron volts.) and the rate of intensity is based on the amperage driving the emissions. As near as I remember my Radiography examinations. These levels are 50 to 1000 times more than medical x-ray film.

The absorbed dosage is also based energy of the radiation. For such things as Cobalt 60 (1.1 Mev), the body absorbs half of the radiation, the rest passes through to the person behind you. The radiation from smoke detectors is much more energetic and harmful than that of the CRT.
Americium 241, 7.5 Mev alpha particles!

Here is the good news:
If you double your distance from a radiation source, the radiation intensity drops by a factor of 4. Called the inverse square law. The distance from CRT face to the body may vary from 50 to 90 cm. So the distance makes a huge difference. Air does absorb many low level x-rays.

Additionally, the half of the dosage absorbed by the body is shrugged of over 24 hours.

The mean lethal dose LD 50 of the population is about 400 REM of radiation, if you get it all at once. Roentgens apply to the radiation and not the absorbed dose. To arrive at an absorbed dose, one must look at the energy of the radiation in Kev, times a compensating factor, and multiply that by the relative biological effectiveness (RBE) of the radiation involved. There are some newer SI conversions, forgive me, I've got grey hair.
By older regulations , general public (unmonitored), was not to be exposed to more than 500 milli REM over the a year period. based on 2,000 hours that relates to 0.25 milli REM per hour. Newer regulations have dropped that to 300 milli REM for the year.

And for the radiation level to make you sterile, it would kill you first, if delivered to the whole body. In the order of 2000 REM. The survivability rate is about 0.015 %.

The cumulating effects, well, the lifetime safe dose is 180 REM, used to be 250. based on 5 REM over 50 years. So sitting in front of your monitor for 300 years 24 hours a day at a distance of 1 cm from the tube; surface constantly, that may cause some problems.

The clothing you wear will help stop the 20- 30 kV radiation . The attenuation factor of the CRT glass is in the order of 4.66 for radiation at 20 Kev and 4.38 for 50 Kev.

Life is a risk, your ceramic coffee cup is just as hazardous, Klysatrons are much more lethal, more from voltage than radiation.

A company I consulted to, was plasma coating pipes, they used a 50 KV power supply at 2000 amps.
I mentioned a possible radiation hazard, and sure enough, they had to wear TLD dosimeters, but other dosimeters did not register such a low energy of radiation.
Have a look at
http://www.logwell.com/tech/nuclear/rad_cheat1.html

If one paranoid about radiation, then get LCD displays!
The stress of worrying about small hazards is much more damaging to ones health than the radiation.

Good health to all.
I just have to get my code speed back up and re-write that exam.

"Strong" beam of electrons, "highly" positive - but how strong, and how high?

Yes, a monitor screen does generate a small amount of low-energy x-rays - but the intensity (rate of photon generation) is proportional to the electron beam current, and the penetrating power (photon energy) is proportional to the accelerating voltage. The radiation dose rate (rate of energy deposition from photons absorbed) is proportional to these two factors multiplied together.

Both the beam current and the accelerating voltage in a monitor or a TV are much smaller than in x-ray machines than, so the radiation dose rate is also much less. Accelerating voltages in medical x-ray machines are typically 80-100kV in order to pass right through the body to the film on the other side without excessive scattering (which is why the x-ray picture using a TV looks fuzzy - the low-energy photons are being scattered). Beam currents in x-ray machines are of the order of 100mA in order to achieve exposure times of one second or less. This makes your TV look very feeble by comparison.

A small x-ray dose rate at the surface of the screen is tolerable because nobody is there to receive it. We say that "our children are glued to the computer screen" but fortunately that is not literally true!

Remember that x-rays are electromagnetic radiation, so the power density from a point source obeys the inverse square law. Further away from the screen, the dose rate is much less than the contact dose. The screen is not a point source, so it is not exactly inverse-square at relatively small distances; on the other hand, a TV viewed from across the room is a pretty good approximation to a point source.

>Here in Europe the X-ray machine is called 'Roendgen' after its inventor

>measuring unit is Rg/h (roendgen-hours).

The roentgen has not been used by professionals in Europe for at well over 20 years - the SI units are the Gray (energy deposition) and the Sievert (energy deposition weighted by biological effectiveness).

>
You are a reasonably concerned parent - but you are also a radio amateur, with enough technical background to know that if you want to really understand something, you need to apply some numbers to it.

>Now, what I am trying to find out in this news group is the
>million-dollar question: "Our childern sit in front of their computers
>for hundreds of hours. Could it happen that they become sterilized, or -
>when they grow up - that they get monster and reterded children like
>those we can see around Chernobil today?" Exact numbers are needed;
>funny anegdotes do not help here.

Exactly - and telling stories to scare yourself does not help either.

>Judging by some answers I have touched
>a wasp nest. I am aware that producing monitors is a multi-billion dolar
>business today. Who should I believe to?

Try the professionals -
http://www.nrpb.org/publications/documents_of_nrpb/abstracts/absd5-2.htm concludes that:

"X-ray emissions [received from monitors, at normal viewing distances] are thousands of times lower than normal background levels of ionising radiation."

Try the same experiment with the film at a normal viewing distance - you will see no effect.

2137. sa612 v passive mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-16 12:46:46 UTC
From: stephen zl1any <g_and_s_pearce@xtra.co.nz>
Message-ID: <3c933e18$1@zfree.co.nz>
Source record: 45576

Why did Elecraft use a passive ring mixer in the k2 rather than
something like a sa602 or sa612?

Thanks

http://www.zfree.co.nz

2138. Re: Radiation from monitors

Ian quotes -
> "X-ray emissions [received from monitors, at normal viewing distances]
> are thousands of times lower than normal background levels of ionising
> radiation."
==========
Ian, quite reassuring. After many years, on and off, sitting before CRT's
it's something which has never bothered me very much. But are there any
other forms of possibly hazardous radiation emitted from computer monitors
which are NOT lower than normal background levels? It is appreciated you
are not a claimed expert in such matters but you may have have studied, more
than most of us, the many reports issued in recent years.

Yours, Reg.

Digi-Key has some 21.4MHz filters that should fill the bill; the brand is ECS, out of the Midwest. They come in 2-pole and 4-pole sets. They are on page 461 of the January - April 2000 catalog. I have used their 10.7MHz filters as roofing filters, with good results.

Hello all,

Do not forget that the N.A.R.S.A. Radio and Electronics exhibition / Rally
takes place tomorrow Sunday 17th March in Blackpool, Lancashire.
There is a Bring & Buy, all the usual traders commercial stands, plus
club stands from the organising societies.

Doors open at :-
10:30 am for the disabled visitors
11:00 am for the general public

Have a good St.Patrick's day and see there

Martin

This might be a little off topic, but I have taken the broadband noise circuit from one of the other ARRL handbooks, and added enough gain after the diode. The result is a noise generator that will put out 0dBm from 10KHz to 1.3GHz, with a flat output across this range. I would be glad to share the circuit, along with board layouts to interested parties. What I use this circuit for is characterizing RF filters, along with a spectrum analyzer.

This could be a little off, but what I do is calculate the Thevinem impedance of the circuit, by calculating the parallel resistance of Rd, and (Rs in series with the channel resistance). This could be derived by measuring Vd, Vs, and the voltage drop across the JFET. I have found that a good rule of thumb when selecting the Drain/Source resistors is to make Rs about 25% to 33% of Rd, if you want the operating point of Vd to be approximately (Vcc/2). I have used this technique when embedding a JFET between a couple of crystal filters, and it has worked ok.
If I am off base, feel free to correct me folks!

Stephen,

Generaly speaking...
Active mixers (like the 602/612) can provide conversion gain unlike a diode ring mixer which typically has about a 6 db loss. Active mixers also require much lower local oscillator drive. These are nice features. OTOH, the diode ring mixers can handle a much larger input signal range. If performance is the primay criterium (over cost), the diode mixer is the one to use inspite of the need for a higher L.O. injection level and more system gain (to balance out it's loss).

HI,

You can use a crystal or a ceramic resonator, detected audio levels with a
normal quad coil are low but could be useable.

another option would be a synchronous FM detector using D type latches and a
21.4MHz oscillator. This works in a similar way to the
"phase detector on PLLs", it generates error pulses with deviation from
centre frequency, you just need an integrator (R/C network to turn that back
into the analog waveform afterwards.

Have used this circuit myself.

you could also try a PLL FM detector too.

Well, not /that/ much, a super-regenerative receiver is like a normal regen with a gain control being racked up and down really fast. The main difference is selectivity, swooshing the gain up and down obviously widens it as there is less Q-boosting from the shorter period of negative resistance.

Super's are also /much/ more sensitive, like 30dB better, but that comes at a price, basically of sampling the wanted signal at the quenching frequency and collecting everything inside the quenching sidebands, and any harmonics of it.

Yes, you can't really do CW/SSB on a super-regen, but you can do NBFM if you try hard, and CW/SSB is possible if you back them off into normal regeneration.

You really need to understand how the noise bridge works, before you
start modifying it.

You have a bridge, consisting of T1, C1/C2, and R1. Your receiver is
the level indicator. You have an unknown impedance, which would often
be the antenna. And you need a signal source.

You can read up on bridges, in books like the ARRL Handbook. The
basics is the same as a resistive bridge, though in the case of the noise
bridge you are dealing with more complex components.

But the basic idea is that by adjusting one leg of the bridge, you balance
it with the leg with the unknown impedance. When the level indicator
is at it's mimimum, you have balance. Since you can calibrate the
components in the bridge, then you can read from them the value of the
unknown impedance.

I passed over the signal source, deliberately. You want a signal
at the frequency where you are operating. If you go looking, you will

find this sort of bridge with the signal source being a low power transmitter, or even the station transmitter. The problem with this is that you need to retune it as you move in frequency; this may mean a bandswitching unit if the signal source is built into the bridge, and unless you put a lot of effort into it, you'll have to keep retuning things in order to keep the signal in the passband of the receiver.

So at one point, someone came up with the idea of a white noise source as the signal source. It puts out more or less constant level signal throughout a large slice of spectrum, so you don't need to retune the signal source.

As for the level indicator, I'm sure if you looked, you'd find similar bridges that used things other than the station receiver. But the usual ham does have a receiver, so it saves costs. Otherwise, you'd need to build up some sort of sensitive level indicator.

Take a look at the 2001 ARRL Handbook, there's a different noise bridge in there. The circuit is probably in other recent editions. You will find the same basic circuit, but with a different implementation. The bridge portion is the same. But it uses an IC to amplify the noise generator, which is a zener diode like the one in the Antenna book. The significant difference is that the noise source is not modulated. (In one of these threads of yours, someone suggested modulating the noise source to help in finding the null. That's what the 555 in the Antenna book schematic is doing.)

And a noise bridge has nothing to do with adjusting SWR. It's a piece of test equipment for measuring the impedance of the antenna (or some other device). The variable R and C are your readouts. The only thing you can adjust to improve things is by fiddling with the actual antenna.

Start at the same place that the above quote came from:
http://www.nrpb.org/publications/documents_of_nrpb/abstracts/absd5-2.htm

This is an authoritative report by the UK 'radiation watchdog'
organization on hazards from Visual Display Units. (However, the subject
of 'radiation' - any kind - being what it is, you can also search the
web to find many contrary viewpoints.)

NOTE: My version of the noise bridge will NOT have the variable resistor and capacitor that the original has. I will operate it by hooking it up, adjusting the antenna for minimum SWR for resonance, and then making any additional adjustments (if necessary) with my tuner.

In other words, the purpose of my noise bridge is to tune the antenna WITHOUT using the transmitter. My noise bridge will be more like the MFJ-212 Matchmaker (http://www.mfjenterprises.com/products.php?prodid=MFJ-212), which does not have the resistance and reactance dials.

That's what I'm thinking. Was curious if there were any app notes out
there that talk about quadrature detection with crystals. I'll check
the CA3089's data sheet.

I used to work on ILS systems in the Air Force. It's a little more
complicated
than that. The system used phased antenna arrays so that there was a set
of
space modulated lobes being radiated.

And of course, a Q of 1000 is fairly low for a crystal. You might try
a crystal with damping. Consider that the series resonance is
normally pretty close to the parallel resonance, but if you use a
crystal whose series resonance is below the band of interest and load
it lightly enough with capacitance, you should be able to get the
parallel resonance where you want, and you can add series or shunt
resistance to adjust the Q.

You could also characterize one of your 21.4MHz filters as a one-port
to see if you get the phase response and impedance you need...if you
do, go for it. You might find that loading the "other" port with some
impedance helps. I don't know; I'm just guessing at things to try.

Cheers,
Tom

Yes! Thanks for the reference, Jeroen! (I always like threads like
that which I learn something from.) The OP here doesn't need that
bandwidth, and in fact needs to get it down to maybe 100Hz to 10kHz,
but the basic ideas are very worthwhile.

Cheers,
Tom

This antenna was used for several years under moderate load (100-200 watts). This unit has been in storage since it was taken out of service and replaced with a directional unit in late 1998. Sold as is, not tested since it was removed from service in perfect working order. $50 OBO.

Hi Jason,

You WILL NOT have R1-C1? It will not be a bridge then. These are (in
order) the reference and compensation for stray capacitance seen at
the "unknown" port; without them, you will never see a balance. Such
sweeping design changes will devastate the circuit, much less
eliminate any chance of accuracy (even for amateur work).

R1-C1 are not user controls in the first place, so you have missed the
intent of the previously suggested design. In other words, the two
designs you've offered are much more alike than dissimilar.

As a matter of practical design consideration, can you present us with
a schematic of the stripped down design of either bridge circuit? It
should reveal ONLY the principal components (black boxes for source
and detector are suitable here for simplicity's sake). Your
discussion through several threads suggests you are not familiar with
bridge topography and this ï¿½tude would be beneficial (and necessary).

Well Jim,

all I can say is 4 angle antenna lobe switching technology dates back
to "VALVE" days used in WW2. We had no trouble auto-tracking
hydrogen balloons in azimuth elevation and range. ERL at WRE in
Penfield South Australia even developed a CW radar system which could
give the pilot ground speed and drift as well as all the other
parameters he was ever likely to need and that was back in 1956.

VARIACS FOR SALE (variac.ad)(3/16/02)

The following variacs are offered for sale from
various estates that our committee ("widow's committee)
of the local club are handling. Accepting reasonable
offers. Digital pix are avail on request. All items
are "plus postage/shipping" but, if we can find a
suitable box/packing material, there is no extra charge
for packing and taking to USPO/UPS. Otherwise, buyer
pays any actual packing charges by the UPS "agency"
Shipping is from north-central Florida (ZIP: 34442).

General Radio Model M2-S25 110V input coil size
1-1/4" x 3-1/4"d, double slider.

General Radio 110v, case size 4.5" x 4.5"d, with knob
& 0-135v dial plate & large knob.

Standard Electric Products Co., Model 6541, 0-135vac
7.5a (1 kw max), coil side: 3" x 4"d

General Radio, 0-135vac, case size: 2.5" x 3"d, with
0-135v dial plate and large knob.

I haveused a single one of these in a commercial transceiver design as the
first mixer to 45 MHz. These can be trimmed with bias for best IP3. rom
memory IP3 is in the low 30 dB range. Havent tried two as a quad bridge
(like diode DBM style)

> > Thanks from Rod VK6KRG

Currently I am testing (not yet using) a pait of 2N3904 small signal transistors in parallel, (separately bypassed emitters) as a single common emitter stage. The IP3 is +35 dBm (measured with 50 ohm meter bridging 10K). This figure is OK. The problem is that the gain is MUCH too high. I only need 10 to 15 dB. The signal is then being remixed to455kHz in two paths and combined in a single IF amp. This is a new TYPE of receiver which on which I have a patent pending. It is to be published by the ARRL in QEX soon. It is also being considered for commercial use IF I can overcome the noise problem. 73 from Rod VK6KRG

Why would that be? Type BNC and Type N connectors of the same
impedance have exactly the same center conductor contact structure,
exactly the same shield conductor contact structure, and if specified that
way, exactly the same dielectric structure.

The only real difference is the way the connectors are locked together
by their external rings, one using the bayonet cam, the other using a
threaded ring. Neither locking mechanism has any effect on the electrical
properties of the connectors. Contact force is provided by the spring
fingers of the respective contacts in both cases, and they are identical.

The *only* thing that a Type N has going for it over a Type BNC is
mechanical ruggedness, and possibly a bit better weather sealing.

I was sure I'd seen a filter used instead of an LC circuit in a quadrature
detector. Somewhere (I really wish I knew where) I have a box with some
interesting circuit boards, including something I bought at a hamfest
that used what seemed to be a filter. I know it was a three-terminal
metal can, and I kept the board intact because I was curious about it.
I was sure I'd seen a diagram or two along these lines, but though I
kept trying to think of where, I came up blank.

Then I thought of checking Rohde's receiver book. He shows a circuit
from KVG that uses a "dual-crystal resonator" as the tuned circuit
in a CA3089 design. It does show simple LC circuits, presumably for
matching, at both the input and output of the filter.

From the text: "Also, the improved stability desirable from a high-quality
communications receiver can be achieved with the use of quartz crystal
resonators in the discriminator circuit. Either amplitude or phase
discrimination can be made using crystal resonators if the frequency and
the Q of the crystals are compatible. The phase comparison detector is
most easily adapted to such an application. A particulary convenient
arrangement is to use a monolithic crystal with two poles. Spacing
between the two resonators on the substrate determines the coupling.
The voltage across the two resonators differs in phase by 90 degrees at
the center frequency, as required for the phase coincidence detector.
Because of the high Q of crystal resonators, the bandwidth of such
discriminators is comparatively narrow."

I'm sure I've seen a crystal used with a CA3089, but I can't say
where. An RCA data sheet that I could put my hands on did not have this.
I suspect what I'm remembering was a later edition.

The passage from the Rohde book reminds me that someone, the name Shubert comes to mind, wrote an article in Ham Radio about 1974 or 75 (definitely before going to the large format), about making a crystal discriminator. Used a crystal and a tuned circuit. It was probably a November receiver issue.

> There is a big difference between a regenerative receiver and a
> superregenerative.
>
> Pete
>
Well we were talking super-regen.

But while the results of the two types of detectors can be quite
different, there is practically no difference in the circuitry.

Because this came up a few weeks back, I went back to read up on
the superregenerative. According to the history books, Armstrong
came across the phenomena when he first came across regeneration,
and somehow he didn't follow it up. Almost a decade later, when
he was doing some work on the regen to prepare for his court battle
over the patent, he came across superregeneration. He didn't try
to soup up the regen, the regen circuit accidentally started
quenching. He fiddled around, figured things out, and the patent was
issued 80 years ago.

A regen detector is ultimately just an oscillator, with something to
control the feedback. Or to go a step simpler, a regen detector is
an amplifier with controllable positive feedback. A superregen is just a
regen with something to modulate it at ultrasonic frequencies.

This is crucial to the discussion, because while a lot of people have
built superregens over the years, because they were simple, I suspect
few have much of an understanding of them. To say there is a big
difference is to inhibit an understanding. If people don't see
the progression from amplifier to regen to superregen, they'll see
the superregen as some sort of black box; they probably know about
quenching but that's it.

Once Armstrong figured out what was going on, he added a separate stage
to do the quenching. In those terms, it's much easier to visualize
what's happening. But it would appear that once the patent was issued,
everyone went to the simplest scenario, self-quenching. It made a lot
of sense in the thirties when components were expensive, and money
was hard to come by, and selectivity wasn't really important. But along
the way people have lost track of that patent, and so you never see
an externally quenched superregen (though once in a while, a passing
mention is made). So for decades, everyone would grumble about
the lack of selectivity of a superregen, and if someone tried to
improve the selectivity it was all focused on the tuned circuit.

But if you modulated an oscillator with a some sort of ramp or
pulse waveform, would you really expect to get a narrow band output?

Self-quenching gives little control over the waveform, or it's amplitude,
or it's frequency. A separate quenching oscillator gives you this,
and when it is external, it becomes a lot more obvious that the basic
circuit is a regen.

That's the whole point of Charles Kitchin's work on superregenerative
receivers. He's gone back, and tried to improve it by dealing with
the quenching. I think all of his circuits are still self-quenching,
but he has made attempts at modifying the quenching waveform, and
he says it helps.

I never saw his Communications Quarterly article on superregeneration,
but I did see some of the follow up letters, where people thought it
was a waste of space. In some ways, it is pretty useless to try to
improve something like the rush box. But at the same time, the process
that he must have used, going back to the beginning rather than trying
to add an extension on decades of ultra-simple circuits, understanding
what is going on and then trying to improve it, is a vitally important
process.

So when some guy talks about finding a "circuit on the ARRL website,
but it had too many parts, so I started taking parts out", he is ignoring
the fact that those extra parts may add to the circuit, and unknowingly,
he is reinforcing the image of the superregen that has existed for
most of the past 80 years.

Right. There's an old wheeze going around that the N connector
was the "Navy" connector, but that's not true. Neil designed the
N connector, Concelman (sp) designed the C connector, and both
collaborated on the BNC and TNC connectors. The history is in
old Bell System Journal articles. I've got them somewhere, stored
in a box in the attic.

The contact geometries are identical, but the contact forces on the
outer-conductor connection are not.

The mating surfaces are very slightly tapered, so the radial contact
force is generated by the pulling-together force between the two shells.
On the N connector or the TNC, you can screw the ring down until the
rubber washer inside the plug is fully compressed. On the BNC (or the C,
which is an N-size bayonet connector) the washer is *never* completely
compressed in the locked position - or else you couldn't make it click
into place - so the contact force is less. This opens up the
possibilities of reduced performance.

The practical difference is that you can always rotate a BNC or a C
plug when it's mated - and as the rubber washer ages under compression,
the contact force on the outer conductor can become very unreliable. You
can't rotate an N or a TNC - even with an old washer, you simply screw
down the ring a little further and the contact force is just like new.

All this is complicated by the amateur's habit of recycling old
connectors (some of my BNCs must have clocked up 30-40 years with myself
and the previous owners, and many of them have been reassembled several
times) and of course we never use a cutting jig to assemble them
correctly. Therefore we get a lot more variation in performance than the
professionals who use new, factory-assembled leads. But as others have

said, that generally doesn't matter, except when we try to make precision SWR/return-loss measurements, measure very low levels of spurious signals, or use very high power.

Going all the way back to the original question, the old 141-series H-P spectrum analysers have BNC sockets on all the RF plugins, up to 1.3GHz. The only practical problems arise from using old or incorrectly-assembled plugs (or 75-ohm plugs)... and all that, you can do something about.

I built a PSK31 audio interface using an MFJ-5213 prewired 13 pin DIN male plug. It sure beats trying to colder to the pins on the back of the plug.

Hi,

I'm looking for a 64 page instruction booklet for the 8051 microcontroller. Its titled "Assembly Language Basics"

It was published by a company called Suncoast Technologies of Spring Hill FL 34606.

The booklet was sold around 1995-96 for $15.00.

If you have this book, please email me at: steve34613@atlantic.net

I would like to purchase a copy. Please email me if you have this booklet; as I am unable to log into these NGs everyday to check for responses.

Thank You
Steve

You'll need some specs first, Joel. What voltage? How much current?
Maximum cost?

Then you need to decide whether you'll be buying new parts or
scrounging, what features you want (like metering, overvoltage
protection, current limiting, etc.), how much ripple you'll allow, and
whether you want the output electronically regulated (though I can't see
why someone would build an unregulated supply nowadays).

You really should start by getting a book that has a decent section on
power supplies and reading that. Doing a little homework will help you
decide what specs you want, and you should then be better prepared to
ask specific questions. I think you'll find plenty of helpful folks on
this newsgroup.

Plugging a type N into a BNC does work but it is not a good idea. (I
can hear more flames
coming) If you look closely the type N center pin is slightly larger
than the BNC pin. It will
distort the center contact on the BNC female. Then when you go and put
a BNC back in it will
sometime not make good contact again.

I have an old HP 141 also and yes it does have BNC connectors on the
rf. There were several
manufacturers that used them in the past. With more recent equipment
where there is more
concentration of work being done in the higher frequencies I think
that the realization is a little
clearer of the shortcomings of the BNC.
Motorola manufacturers a service monitor that goes to 1ghz. The common
cable used by the
radio people using the unit is bnc. I asked the Motorola engineers why
they did not supply the
unit with a BNC connector as they do ship an N to BNC adapter with the
unit. The answer was
that it was impossible to reach the flatness response spec above about
700 mhz.

Sounds like you're trying to build a return-loss bridge. Works good with a spec-an with a TG. Zach Lau did a couple of articles for QEX a couple of years ago describing the use and construction.

Yes, sorry - you're right, they are similar enough to be almost
compatible, but not identical. Putting an N plug into a BNC socket is
not a good idea anyway, because there is nothing to hold the two
connectors together.

Like other contributors, I find that statement surprising. For a
non-precision instrument operating only up to 1GHz, BNCs in good
condition should be plenty good enough. On the other hand, it might seem
more reasonable if they had qualified the statement in some way, for
example by saying that it was impossible to do it reliably, in the long
term, and/or with worn-out BNC plugs.

So they use an N connector on the instrument, and then supply an N to
BNC adapter... yeah, right...

take al look at this site:
http://www.mitedu.freeserve.co.uk/Circuits/Power/l200.html
here you will find a nice powersupply.
The 4 arrows on the left site are diodes. You can buy 4 diodes sepperatly
or one block. On this block you must glue a heatsink with special glue.
The bigger the heatsink is the better it will cool the block. The inventor
of
this system is Greatz. He invented a way to invert the sinus-current into an
pulsing directcurrent. There must be websites about him.

The electrolytic capacitators (4700uf and 10uf) are only working well if you
place the positive and the negative pins right.= polarity-sensitive
If you don't then you blow the electrolytic capacitators up.
It is easy to see what the negative pin is. It is marked with -
The other capacitators (100n and 100n) are not polarity-sensitive.
The resistor are also not polarity-sensitive.

If you made this powersupply you can ask someone to measure how flat
the outputcurrentcy will be. This you can do with a oscilloscoop.

have fun.

I recently purchased a nice, used FT-101EE. The radio appears to be working except the AM receive is distorted. I recently read that there is a way to add a separate 6 Khz AM IF filter that will cure the problem but upon checking the prices of the Fox-Tango filters, I'd like to find an alternative (I paid less for the radio than the price they are asking).

Appreciate any thoughts here and thanks, in advance.

Did you replace it with a NON-POLARIZED motor run capacitor?
That is an AC cap, and 5-mfd will not make a difference. Lot at the
tolerance ratings.

If you actually measure things, you'll find that the N bottoms on the shell
faces before bottoming the contacts. So in reality you can't tighten it any
more than a BNC. The only difference is that you can't feel it, because
the shell has bottomed. (Note, the shell plays no part in the electrical
performance of the connector.)

This situation only exists if you try to plug a 50 ohm N male into a 75 ohm
BNC female (Yes, they come in two different impedances). The 50 ohm pin
is bigger than the 75 ohm socket. For same impedance connectors of either
series, the pin diameters are *exactly* the same.

The more likely cause of damage when pushing an N male onto a BNC
female is that you will *cock* the connector while inserting it. This will
damage the center female contact.

Note, both of these connectors are considered *assembly* connectors.
After a few plug and unplug cycles, they *will* become loose, no matter
what precautions you take. Good quality connectors used carefully can
last a few hundred plug/unplug cycles, but you do have to replace them
periodically if you do much plugging and unplugging.

When I first heard that I was kind of surprised myself. But I have heard similar from other
manufacturers too. I had always viewed the N and BNC as very similar connectors. But it
seems that as you approach 1ghz things get a little trickier. The service monitor in question is
specked at +_ 2 db from 400 khz to 1ghz. Supposedly in order to maintain the +_ 2db they
had to use an N connector. Most all of the end users would have preferred the BNC connector
as that seemed to be kind of the standard with most shops. In the early days of 800 mhz radios
it was difficult to find an N connector jumper cable in a 2 way radio shop. Most all equipment
had uhf connectors and most test equipment had BNC connectors. When the service monitors
with N connectors came in the door everybody complained about it. Motorola was asked to
supply the monitors with a BNC connector but would not do so. The solution to the problem
was to supply the N to BNC adapter with the equipment. The spec is with the N connector
only. No adapter.

Now once the shops got heavily into the 800 and 900 mhz equipment, most all now use a
proper cable with the N connector for the higher frequencies.

It is absolutely true that they supply an N to BNC adapter with each unit as a standard included
accessory. I used to sell them for a number of years.

Hi Jason,

First the concept of the bridge. It exhibits a null to the detector when all four arms are balanced with respect to each other. There are many respects and many topologies to observe these relationships; however, when you boil down the designs, they are all closely related if not identical - hence my suggestion for you to reduce those circuits as an exercise. You will find much enlightenment in such an exercise still, even after my lucid explanation. :-)

Being able to "see" an opportunity for a bridge solution for a measurement problem is ALWAYS preferable. A balanced bridge presents absolutely no load to the item being measured and by this becomes invisible to the process. Bridges bring isolation, sensitivity, resolution and accuracy. To illustrate, you may not be able to afford a DC or low AF (audio) AC meter with 4 place accuracy (not to be confused with 4 digit display); but you may, with work, build an inexpensive bridge accurate at AF to 6 places and very respectable in HF. Note, as you depart from low frequencies, instrumentation accuracy plummets, and bridge techniques become even more necessary.

Second, the balance of the bridge. This may obtained by holding the "unknown" constant while you derive its value by the inference of control settings (what you have in mind in some sense, and perfectly justified). OR, the balance may be obtained against a constant reference by adjusting the "unknown."

This second method is cheaper to manufacture, calibrate, and simple to use. The first requires cumbersome shaft coupling for critical, large component placement; and (for precision) special shielding to balance

stray coupling.

Third, the source of white noise. By strict definition, white noise is constant in amplitude at every frequency. This again is a commercial consideration in that the designer need not build an extra stable source capable of wide frequency span. This last requirement of stability, as you may now guess, is strictly required if you are to seek and hold a sharp, deep null (it is an absolute pain to chase a drifting source).

Fourth, the operation of a noise bridge. As I said, R1-C1 are the reference and you should note that the ARRL design (and perhaps the MFJ) adds a 100 Ohm resistor to the "unknown" port. This means that without ANY other connection made, the bridge is already in balance. If you observe otherwise, it means that C1 is not adjusted correctly. This presents a simple, one-time solution for that problem by simply tweaking C1. Now, once observing this verity (the already mentioned null) and adding your reactive load to the 100 Ohm resistor at the "unknown" port, you run the risk of unbalancing the bridge if that reactance upsets the effective 100 Ohm requirement. You then rebalance the bridge in one of two ways. You shift your receiver's frequency until the noise abates, or you shift the component that presents the reactance until the noise abates at the original frequency. The first method determines the resonate frequency of the "unknown." The second method forces the "unknown" to resonate at the original frequency. This, of course, presumes a parallel resonance that presents infinite impedance whereupon the 100 Ohm resistor seems to be the only component residing at the "unknown" port (and balance is assured).

Note the emphasis on parallel resonance (it simplifies this instruction). This works with traps, but is not indicative of antennas (except for halfwave). This may sound like a paradox for the intended application, so there are other considerations to be observed in either the application of the bridge, or in its design. The observance and cogitation of those differences are left as an exercise.

The upshot of this all, is that you need to think abstractly in terms of the bridge topology, its design requirements, its actual design, and its application. Reduce all design issues to the bare minimum and replace the "unknown" with a simple L-C-R configuration to determine just how well the bridge may perform. Playing with a SPICE emulator like Electronic Workbench would do wonders to illustrate these concepts.

Well I don't think that is right. I just went and dug out some N and
BNC connectors including
some 75 ohm and 50 ohm BNC's. Both the 50 ohm and 75 ohm BNC's have
what appears to
be exactly the same size center pins on the male plugs. There is a
difference in the body size of
the center pins though. The 75 ohm ones are bigger! But the part of
the pins that mate with the
female jacks are the same size.

The center pins on the type N connectors (the part that mates with the
female jack) are in fact
larger than the BNC pins. So that makes them incompatible. Yes they
will plug in but as I stated
before it will damage the female jack to plug an N into a BNC.

Looking further at the N and BNC center pins, the N center pin's body (ahead of the mating
part) is also much larger than the equivalent part of the BNC. While the outer contact (coax
ground) is the same as the BNC! This larger part of the center pin in both the N and BNC
connector is located partly inside the ground shield. This part makes up a short length of solid
coax cable. So with the outside being the same diameter on both connectors and the center pins
having different diameters, it is impossible for them the both have the same impedance
characteristics. Although at low frequencies this short length (about 1/4") has little effect, at the
higher frequencies it would seem that it would come into play.

2217. BC100XLT repair

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-18 03:51:26 UTC
From: ballgofar@retardsrule.com
Message-ID: <302f180.0203171951.5b8de32c@posting.google.com>
Source record: 45459

Can you tell me how to find this Q201 everyone seems to be talking about?
I have a BC100XLT that has all the symptoms of this seemingly coomon problem yet I dont know how to locate it on the board. Any help would be greatly apprciated. Someone HAS to have done this repair?! PLEASE HELP if at all possible.

Thanks,

Paul

Uniden/Bearcat BC200XLT Portable - Loss of Audio and Dial Lamp
If you can program frequencies into your BC200XLT but there is no audio and
the green backlight no longer functions, a tiny transistor may have failed.
Check for a defective PNP surface mount transistor, Q201 (2SB815B6-YDY).
Q201 is used as a switch to furnish 8 VDC to several stages of the BC200XLT.
Its main purpose is to switch off power hungry stages of the BC200XLT when
the CPU thinks the NiCd voltage has fallen below a threshhold. That's an
attempt to limit the current drain on weak NiCds to avoid permanent damage.

Q201 is located on the foil side of the "Micom" board, adjacent to the black
multi-pin connector which mates the Micom and main boards together.

Q201 can be destroyed by a few different causes, primarily, by something in
the scanner drawing too much current through it. In one case, capacitor C36
shorted. It's a 220 uF 10v electrolytic, located on the component side of
the main board, connected from pin 8 of the audio IC (IC2 NJM386SL) to ground. Capacitor C55 shorted in another BC200XLT. Gary Bean reports he
substituted a 2SA1298 for Q201 and it worked fine. In a pinch you bypass
Q201 by soldering a short piece of bare wire between the collector and emitter, but you must first fix the component which caused Q201 to fail

You might want to modify the fraudulent description of the frequency range you have given it. My Celwave (and Tessco and Hutton) catalog says it is 18 MHz wide, manufactured somewhere between 118 and 174 MHz, like either of the standard models, 146-164 or 154-174 MHz. Where on earth did you get the idea it would work from 25 to 299.9? From the catalog index? Sorry, it doesn't work that way.

You're probably not just imagining it. RCA shows a double-tuned
circuit for the quad network in some of its data sheets. The
double-tuned circuit presumably gives better phase linearity than a
single-tuned circuit with the same total phase differential over the
bandwidth.

Cheers,
Tom

Hi,

I am, too, worried about radiation from monitors, but you can forget
about it, because in a very short time (months to a couple of years)
most people will be working with TFT flat monitors, and these, AFAIK,
don't emit any harmful radiation.

OTOH, what you should worry about for the time to come is the myriad
of wireless devices you will have on your desktop. Yes, I know that 30
mW is very little, but when you have 10 of them (mouse, keyboard, pc,
printer, scanner, laptop, pdaï¿½) that will amount to 300+ mW being
radiated in your close vicinity (less than 1 meter) PERMANENTLY for 8
(..10 ..12?) hours a day for years. Yes, I know these devices are
supposed to reduce power to minimum required themselves, but I have
seen most people "turn up" power to maximum "cause this way is
better".

Now, I am not sure _long_ exposures to 300 mW @ 2.4 GHz are of medical
consideration, but until I see some _serious_ studies (long term, long
exposure effects) made by someone who I can believe to be
_rigorous_and_unbiased_, I won't be happy about it.

2230. KK7B T2 alignment help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-18 18:35:25 UTC
From: jehancoc@pacbell.net
Message-ID: <a95870c1.0203181035.729083c1@posting.google.com>
Source record: 45472

I bread-boarded the KK7B T2 phasing exciter and I am trying to tune it. I only have a DC receiver to listen to the signal but I have a 300mhz scope and I am using a PC sound card to generate signals.

The output into a 50ohm resister looks o.k. except for 20mv carrier leakage due to grounding. This goes away if I remove the connections to the mixers from the audio board.

I also don't have the output filter on it since I plan on boosting the output to 5w.

I am using the twisted-wire quadrature LO phase network described in QEX January 98.

When I run a two-tone (800hz and 1800hz) into the exciter, I get a nice eyeball pattern that I can adjust with the drive. I also noticed that I can peek this with the T2 audio balance

Putting a single tone into the exciter, I don't get what is expected according to my 1970 copy of SSB for the radio amateur. (alright, so I've been out of this for a while) According to that book, I should see a relatively flat, broadband type scope display, with no ripples on the top or bottom edges.

I can stabilize the display using the variable sweep on the scope. The top edge looks ok. The bottom edge has a sine wave loop that sticks out from the broadband image. Something like this:

```
--------------------------------

----\ /----\ /----\ /--
\--/ \--/ \--/
```

No adjustments make this go away. It looks like it is the 800hz tone of the two-tone test.

I can change the single tone into an eyeball pattern by swinging the balance full clock or counter clock. Does this make sense?

When I measure the LO phase it look almot perfect at 90 degrees. The SBL-1 mixers both have a slightly distorted signal at the LO input of about .65 volts. I assume this is due to the diode clipping/loading?

The audio looks really close to 90 degrees when I adjust it using the balance control. I assume for best sideband suppression and carrier null the audio inputs to the SBL-1 mixers should be equal?

Anyway, can someone give me a few hints as to what is going on and/or suggest a way to tune this with building a single image receiver?

Thanks in advance.

2231. In need of a PCB Manufacturer

AP Circuits is recommended by the writers of a couple books. Their prices look good. I have used www.expresspcb.com and the turnaround was exactly as described, but they weren't as inexpensive as the former.

2233. Alinco EDX-2 with any radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-18 20:14:02 UTC
From: Owen Duffy <owen@oda.com.au>
Message-ID: <3C964A8A.764DE714@oda.com.au>
Source record: 45475
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

The Alinco EDX-2 is an automatic end-fed-wire tuner that integrates with a couple of Alinco HF radios, including the DX70-TH.

I am aware that some folk have used this tuner independently of the Alinco transceivers.

Has anyone information on the protocol for controlling this antenna tuner so that I can make a controller that will allow it to be used safely and reliably with other radios?

Thanks... Owen

If you are talking about the RCA CA3089, that device dates to
the early 1970's ... there are much better solutions available.

> The
> double-tuned circuit presumably gives better phase linearity than a
> single-tuned circuit with the same total phase differential over the

This is true ...

On the issue of "filters" there were also some XTAL and Ceramic
resonator-based parts designed to replace the "quad coil" in the
same sort of detector ... their advantage was fixed tuning and with
higher Qs, larger recovered audio swings.

If you find an early Tektronix manual, it will refer to BNC connectors
as "Baby N Connectors" in the parts list. I don't think this is really
where the acronym come from, but I'll bet that it started the
confusion. Most likely this was an inside joke or just jargon among
Tek employees at the time

This post was so good that I've been saving it since 1996:

2240. MMIC questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-19 00:57:52 UTC
From: RaOuL <russ@bit-net.nospam.com>
Message-ID: <H2wI8.636$_T4.5665@news.bit-net.com>
Source record: 45481

Hello All!
I was at a job interview today for a microwave technician job and the subject of MMIC was brought up. I sheepishly admitted that I know nothing about MMIC and politely changed the subject. Overall I believe that the interview went well and that I'll likely be working with MMIC in some capacity in the near future. That brings me to my questions:
I know nothing about MMIC - is there a primer online somewhere? A quick search of Google didn't turn up much useful info for the newbie or casual experimenter. Are there any MMIC development kits available for the casual experimenter at a reasonable price?
Thanks in advance for any information...

MMICs=Monolithic Microwave Integrated Circuits. Generally seems to be used to refer to ICs that combine RF amps with broadband Z-matching components required to interface them to 50 ohms. When you use a MMIC in a 50-ohm system, you generally don't have to worry about designing your own matching networks. But you also won't get the bleeding-edge power consumption and noise-figure specs with MMICs that are possible with discretes, since the low-level aspects of the circuit design are no longer in your hands.

Spend some time at www.minicircuits.com browsing their app notes on their MAR- and ERA- series MMICs for a good introduction. Also, consider bumming free subscriptions to magazines like RF Design if you want to sound like you know what you're talking about in job interviews.

> Cheers,
> Tom
>

Thanks to all for the suggestions... I did have a look at the phase response of the filters, and it seemed pretty twitchy at first glance. It's clear that some matching work would have to be done to make them happy, and even then I'd probably be second-guessing the quality of the recovered audio from now on.

I decided to add a third conversion to the receiver to get down to 455 kHz, where the SA604's boilerplate app note circuit will suffice.

2243. Parts/Design for 50V, 25 Amp DC Pwr Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-19 01:33:29 UTC
From: Bill Kirkland <kirklandb@sympatico.ca>
Message-ID: <3C969568.2927A167@sympatico.ca>
Source record: 45484

I am looking to build a 50 V 25 Amp DC supply for a 600 Watt Quad Fet Amp -
basically the one in the Motorola Ap note.

Any suggestions on a design and parts procurement?
Particularly surplus parts.

I don't feel like spending the 1.5K for a commercial switching unit.

Hammond makes a toroidal transformer which with paralleled secondary windings will produce 60 V at 25 Amp. (115Vac Primary).
Any alternatives?

Finding a good filtering capacitor with lots of uF and a good voltage rating
looks expensive. I figure it should have a voltage rating of at least 125V given
that the peak of 60 V rms is 90 V.

Suggestions on regulating circuits? The classic 723 is only good for about 40 V DC.

thanks
bk

Hi Jim,
I believe you can get any back issue article from the ARRL, for a fee,
of course.
You can also get the article from FAR Circuits, when you buy the PCB's
for the antenna project from FAR.

For copying/postage costs, I could also run a copy of the article for
you.

From: stephen zl1any <g_and_s_pearce@xtra.co.nz>
Message-ID: <3c969d08@zfree.co.nz>
Source record: 45486

Hi
Any suggestions for an incircuit programmable dsp
with flash ram to serve as the backend of a digital if receiver?

I plan to use bpf/first mixer/ crystal filter then
ad9870 if processor with second crystal if ... as a sw freq reciever.
the first lo will be pll and have fine freq resolution to get round the 6.25
KHz spacing limitation of the on board synthesiser in the ad9870.

The ad9870 output is a baseband digital bit stream incorporating
i and q data vectors and selectable agc information (to give effectively
higher
dynamic range)

I was looking at the dsPIC30F processors .. particulary
dsPIC30F6012 .. but these will not be available until later this year ...

Has anyone suggestions on an alternative dsp capable processor to processes
the base band bit stream and drive a codec
for audio output

Thanks

Stephen

2246. PCS64i used for Phasing SSB alignment

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-19 02:20:34 UTC
From: jehancoc@pacbell.net
Message-ID: <a95870c1.0203181820.53b722eb@posting.google.com>
Source record: 45487

Rick, KK7B of R2/T2 receiver/transmitter fame, gave me a suggestion today about aligning a phasing type SSB transmitter. He suggested down-converting the output of the SSB transmitter by mixing the output with a 10khz signal and using a PC soundcard and spectrum analyzer software to set the phasing balance.

I own one of Velleman's PCS64i PC digital storage scopes and use it for transients, I/R signals, audio spectrum (though Soundforge and a PC card do a better job at audio spectrum). I think I paid $200US for it. I use a 300mhz tektronics most of the time.

Rick's suggestion of mixing the signal prompted me to lower the sample rate of the PCS64i spectrum analyzer from 16mhz (which I use for 7Mhz) to 80khz. At 7mhz, you can only see the carrier and carrier harmonics. The under-sample gave me a nice display of the 7mhz spectrum translated to roughly 45khz on the display. I haven't worked out the math for the translation. The sidebands tend to flop from upper to lower depending on the sample rate selected. I was able to clearly see the audio sidebands and harmonics. The audio offsets by frequency were as close as I can measure. I was using 800/1800 two-tone and single tones from 500-2500 and they were right on. I then tuned the T2 audio phase balance and watched as the opposite sideband was minimized.

This "added feature at no extra charge" made the PCS64i much more valuable. I don't know how accurate the DB and voltage calculations are when under-sampling, but they match as far as I can tell.

As to the T2, I am getting over 40db of carrier suppression and over 30db of opposite sideband with a breadboard, jumpers and all kinds of leakage. I think I can get to 50db of carrier based on eliminating the leakage picked up on ground. I haven't figured out the opposite sideband suppression since that should be greater.

Rob,

I have the complete service manual set for alliance rotators,
including the U-100.
Can scan and send if you like...
Four 8 1/2 x 11 pages devoted to the U100. Would be a medium large
file set for decent resolution, even w/jpg. Let me know if you still
need / want the files...

In general, the bandwidth of the filters in the lowest frequency IF
stage.

I take it you want to listen to weather satellite signals.
The bandwidth is generally set by a filter in the IF strip
Generally the 138 MHz signal will be mixed with a LO of (say) 148.7 to give
a 10.7 MHz signal which is amplified by a high gain IF strip with amplitude
limiting so that all signals come out at the same strength. You can get
suitable ceramic or even crystal filters which are inserted in the IF strip.
A detector then extracts audio from the frequency variations of the signal
The audio is processed by a further circuit or computer to give the picture.

Okay thanks for the explanation. So I suppose i could take any good quality FM circuit, and chance the filter to the right width? Does it matter if the filter is wider than 45khz and is it possible to get a variable bandwidth filter? Thanks,

David

As you probably do not have too many signals to seperate you can
probably use a wider filter. One modification that has been made on
some of the scanners is to take out the narrow 455 khz filter and put a
capacitor of about .01 uf in its place.
Finding filters for other than the FM broacast band which I think are
around 200 khz or wider than 15 khz may be difficult. YOu may want to
look at www.hamtronics.com for a receiver .

the only problem I am aware of is poor isolation between output and
input, so if output termination is poor this reflects to the input.
Therefore is not recommended to terminate a mixer (and feeding an xtal
filter), then an extra transistor output stage is needed, but the
modification is rather simple, and the transistor may be connected to
use same current as the amplifier.

2262. Low Output Impedance DC Amplifier Chip

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-19 18:51:15 UTC
From: martin@okstate.edu
Message-ID: <a781b3$i4p$1@hydrogen.cis.okstate.edu>
Source record: 45353

Someone gave me a circuit description that splits a
single-ended DC supply in to two half-voltage supplies for
running differential op-amps. The circuit used a LM381 low-noise
amplifier biased in such a way as to produce an output exactly
halfway between Vcc and ground.

The only problem is that the LM381 is no longer made.
The exact same circuit should, however, work on any DC amplifier
chip that has a low noise output figure and, this is the
important part, has a very low impedance. The output of the
amplifier is the fake signal ground for one's op-amp circuitry so
the duel-ended supply voltages are gotten between the output pin
of the voltage amp and each end of the DC supply.

Are there any amplifiers that might handle 20 to 30 volts
and dissipate a watt or two?

That much dissipation would probably not be needed, but a
margin of safety never heart anybody.

The other alternative is to take something like a 741 set
to unity gain, bias its + input from a pair of equal resistors
across the DC supply and feed the output of the 741 to a
PNP/NPN transistor pair whose emitters are the new 0 point.

A chip with low enough impedance would negate the need
for the external output pair.

Hi all. I think I might be able to figure this out on my own, but I'd like to avoid reinventing the wheel if possible. I can't seem to find anything by searching on the web, so I'll ask here.

I want to get a speaker/mic made for ICOM/Maxon type handhelds to work with a Motorola commercial handheld. The Motorola is an LTS2000 and has the same speaker/mic as the GP300 series. Basically the speaker is always connected, and the PTT is just a switch in series with the microphone. The radio senses when you close the switch, and then goes into transmit. Any ideas? I'd like to build a seperate box to do the conversion, that way the speaker mic will work on both units.

Any and all help or pointers for info will really be appreciated. If possibly, can you also cc a copy of your reply to joshy@3mtmp.com? My newsgroup access is really bad.

Thanks in advance!

One thing worth keeping in mind is that since you seem to have good
filters at the 21.4MHz IF, you don't need anything beyond a filter
to remove the unwanted outputs of the third mixer. That loosens
things up, because you could convert to any frequency low enough
for good discriminator operation. Significantly, you can then
get away with using a crystal that would be commonly available,
rather than having a crystal ground to take 21.4MHz to 455KHz.

A small thing, but I have a bunch of odd-ball frequency filters
that aren't such a bargain if I have to spend money on a custom
crystal to convert to another IF.

I'm pretty lucky in this case because both my 1st and 2nd LOs and my BFO are fully synthesized, allowing me to put the IFs anywhere I want. I was initially hoping to avoid a third conversion, but that turned out to be more trouble than it would have been worth, for SSB as well as NBFM.

The overall conversion scheme is looking like 904 MHz 1st IF; 10.7 MHz 2nd (and final) IF for WBFM; and 32 MHz 2nd IF followed by a 455-kHz 3rd IF for NBFM, AM, and SSB.

Message-ID: <3200347.0203191731.710f8048@posting.google.com>
Source record: 45360

Now wait a minute here! The LM381 is a dual audio PREamp, not a power amplifier. It has an open-loop output impedance of 150 ohms or so, and you can find plenty of op amps that will beat that. You can also find plenty of op amps that have low input-referred noise. The LM381 is around 5nV/rtHz, it appears, and you should be able to do about as well with a 5532/5534 op amp, which ought to be pretty cheap. You can get to lower noise in many other parts, though they get a bit more pricy. (I have a bunch of LT1124's I scrapped out of some boards that look like they'd be quite good in this application, for example. Low noise, will handle the voltage, can sink or source 20mA, high gain, reasonable bandwidth. Only other thing that would be nice to have is the ability to directly drive large capacitors with unity gain feedback connected.)

Do you think you really NEED that sort of power dissipation?? From the schematic in the data sheet, it looks like the LM381 is current-limited at around 12mA sourced, and at 15V drop, that's only 180mW. You can do better than that in a lot of modern op amps, both in power dissipation and output current limit. If you need power, it's likely because you want a reference to return a low-impedance load to, and in that case, you might do better with a bridged dual power amplifier.

Just AVOID the LM324/LM358 type op amps for this application. Speaking from bitter experience, they have a severe problem if you ask their output current to change polarity, since the output stage is (nearly) class-C. (They can work OK, though not terribly low noise, if you provide a resistor to bias their output current to be unipolar.)

Also, it's not a bad idea to design your circuits so they don't need that node to be super-low impedance, and to decouple things from possible high frequency crosstalk among the various things tied to that node.

Cheers,
Tom

I'll offer some random thoughts on what's a pretty open-ended topic...

Unless you use a choke-input filter, 60V RMS will give you lots of
voltage to drop to get down to 50VDC output!

I'd highly recommend using switching techniques somewhere along the
line...if not straight off the line, at least in regulating the DC out
of the mains-frequency supply. Otherwise, be prepared to dissipate a
lot of power in your regulator. I'd actually avoid trying to use too
large a filter cap; it will increase the RMS current in the
transformer secondary with very little increase in output voltage.
Best use of the power transformer, though, is with a choke-input
filter. You'd also get pretty decent regulation straight out of the
filter if you used, say, a 10mH choke and kept the current to at least
about five amps.

I'd personally do an off-line switcher. Note that per unit of energy
storage, caps rated appropriately for off-line rectification are
considerably cheaper than ones appropriate for 60V rectification. The
power transformer is vastly smaller and lighter at 100kHz than at
60Hz. You can turn the supply off during receive to avoid the hash.
The power mosfets to drive the transformer aren't terribly expensive
(~10A, 400V parts), and modern control ICs give you good design info
and current-mode control that inherently limits current. There are,
of course, a lot more pitfalls than with a heavy-iron solution, but if
you can get the amplifier working right, I'd think you can get a
switching supply working too.

Cheers,
Tom

I think they flew one around in the astrodome one time. I think I've
seen the video to it . Was years ago. MK

2271. rudolf hell (hellschreiber inventor)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-20 04:26:15 UTC
From: Monty Brandenberg <mcbinc@ne.mediaone.net>
Message-ID: <3C981017.B1657487@ne.mediaone.net>
Source record: 45364

From Thursday, March 14, 2002:

BERLIN (AP) -- Rudolf Hell, a German inventor who pioneered technology that led to the fax and the color scanner, has died, officials said Thursday. He was 100.

The announcement came from the northern German city of Kiel, where Hell rebuilt his business in the 1940s after his factory in Berlin was destroyed during World War II. No cause of death was announced.

Hell's landmark invention was a machine for transmitting text that electronically broke up letters into a stream of dots reassembled at the receiving end, in effect the first telefax.

The commercial success of his 1929 "Hell Recorder" allowed him to found his own company.

The technology was less prone to poor reception than telex transmissions, making Hell's machines popular for news agencies, the post office and police departments. In the 1920s, he also invented an image scanning tube for televisions and a radio-beam flightpath finder that is considered a forerunner of aircraft autopilots.

During World War II in Nazi Germany, Hell worked on encoding machines. After the wartime destruction, he resumed business in 1947 and came up with inventions that revolutionized the graphic arts.

An electronically controlled engraver unveiled in 1954 made photo publishing easier for newspapers, and an early version of the color scanner followed in 1963. Hell also was a pioneer of electronic digital typesetting in the 1960s, which ushered out the traditional method using lead.

Hell sold his Kiel-based company in 1981 to German industrial giant Siemens. It was later merged with Linotype AG to become Linotype-Hell AG, which in turn was taken over by German printing press maker Heidelberger Druckmaschinen in 1996. Hell retreated from his business over the past decade.

Born Dec. 19, 1901 in the Bavarian town of Eggmuehl, Hell excelled in physics and math in school. He held a doctorate in electronic engineering, a then-fledgling field he studied in Munich in the 1920s. The West German government awarded him its highest honor, the Grand Cross of Merit for Distinguished Service.

There was no information on survivors or funeral arrangements.

New transistors, 10 each, matched set.

Alternate part number is NE050297-07.

These transistors are NEW!

RF parts wants about $27.00 each.

You can have all ten for $175.00 plus shipping.

I'm working on something similair here and am using a TMS320VC32.
It is not incircuit programmable but incorporates a boot loader so booting
it from an external FLASH isn't too difficult. There's no problem ordering
them in single quantities (in the netherlands) and the're quite cheap.
Furthermore, there's a lot of software available.

2276. Phasing SSB exciter - audio second harmonic problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-20 16:10:04 UTC
From: jehancoc@pacbell.net
Message-ID: <a95870c1.0203200810.426f3d7e@posting.google.com>
Source record: 45367

I built a KK7B phasing exciter. I tried the original and updated audio phase shift circuit but used a twisted-wie quadrature LO phase splitter. Both circuits performed well with carrier down a little over 50db and opposite sideband down about 40db with a breadboarded ground system.

I then swapped out the entire audio phase shift network with a motorola 56309evm dsp running the audio filters and hilbert transform. The signal is very much improved in the desired sideband and the opposite sideband is now down 45db or so. Carrier suppression stayed the same. The two-tone test displayed very little audio harmonic content in the desired sideband opposed to the other two audio phase shifters where the odd harmonics were detectable.

I can tune the opposite sideband so that the fundamentals in the two-tone (and single tone) are reduced over 50db, most likely 55db. The problem is that when the opposite sideband is balanced out, the fundamentals drop but at a point, the second harmonic of the fundamental audio starts to rise and limits my overall opposite sideband suppression.

What is causing the second harmonic in the opposite sideband to be so prominent?

I haven't had time to explore this mathematically. Can it be reduced?

The second harmonic problem is the same with either single or two-tone drive. I am not overmodulating the carrier.

Thanks.

Many thanks for all the information. Since I posted that
message, I have found out about a little chip that Texas
Instruments makes called the TLE2426

http://www-s.ti.com/sc/ds/tle2426.pdf

It is called a rail splitter virtual ground device and it
divides a single-ended supply exactly in half and gives you a
source or sink of 20ma. They make several suffixes for different
operating temperature ranges and package designs, but the device
which Digikey carries sounds like what I needed all along.

It is good from 4 to 40 volts and one of the packages is
a 8-pin DIP that brings a decoupling pin out to allow for a
capacitor to ground to reduce the output noise.

Again, thanks for the pointers, etc.

That sounds sweet, but I haven't even been on the air since about 1995, yet
alone HF.

Is it true, what I hear, that amateur radio has been dying out lately, due
to cell phones of all things? You can't exactly have QSO's with people all
over the world, using cell phones.

Check out the article in QRP Classics, from July 87 QST
Designing and Building Simple Crystal Filters
some notes
larger C values yield narrower BW and higher insertion loss
vary the end terminations to obtain a shape that is free of passband
ripple.

The ARRL handbook may still have a circuit for sweeping crystal filters.

2289. Wideband Amp Tests

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-21 05:42:01 UTC
From: Steve Ratzlaff <sratzlaf@flash.net>
Message-ID: <3C997223.1ECB553D@flash.net>
Source record: 45379

I've just finished testing a breadboard wideband amp from an old RF Design article that I somehow overlooked all these years. The article is from the February 1989 issue of RF Design (an industry trade journal, free if you work in electronics), titled "A New Negative Feedback Amplifier" by Victor Koren (of Tadiran in Israel). I was sent a copy of the article recently, but it looked vaguely familiar, and sure enough, I had the original article torn out and saved (in my vast unsorted pile of paper--which I waded through looking for the article, and found it). Re-reading the article, it didn't look all that promising, but the actual prototype circuit looked easy enough to duplicate.
Instead of classic negative feedback amps using transformers, this article claims use of a directional coupler to improve reverse isolation. The original prototype used an MRF587 bipolar transistor. I didn't have one of those, but I did find an old MRF586--the same die as the 587, in a TO-39 case. I used FT37-75 cores for the input directional coupler and the output bifilar transformer. A 1:10 turns ratio for the coupler was used in the article's circuit. I used the same turns ratio, using an actual 2:20 turns to get a hoped-for lower frequency response. The bifilar output transformer used 16 turns for each winding.
I used test equipment at work to measure gain, response, IMD; and a calibrated signal generator with communications receiver and audio voltmeter at home to measure MDS and derive noise figure.

The circuit worked immediately and was unconditionally stable (input or output or both open circuit or terminated), using a 1.5GHZ spectrum analyzer to check for instability products. Bias was set for 35mA with a 12.8volt supply. Performance of the single-ended circuit turned out to be quite good.
Gain was about +10.5dB, being very flat over a wide bandwidth, with a slight peaking of +11.0dB from 58-104 MHz, with +11.6dB peak at 82MHz using my cores and suspended-over-a-groundplane circuit construction. At the low end, response was down -1dB at 75kHz; -2dB at 48kHz; -3dB at 35kHz--pretty good LF response for only 2 turns on the directional coupler primary.

Reverse Isolation was very good-- 38dB from 225kHz to 30MHz, dropping to 30dB at 95MHz and 29dB at 110MHz.

Return Loss, both input and output, were both very good; in fact, input RL got slightly better when the output termination was removed; output RL got poorer when input termination was removed, which is what's normally expected.
Input Return Loss--250kHz 15.4dB; 500kHz 21.8dB; 1MHz 25.4dB; 15MHz 24.5dB; 30MHz 20.4dB 50MHz 14.2dB.
Output Return Loss--250kHz 24.2dB; 500kHz 24.5dB; 1MHz 24.8dB; 15MHz

22.4dB; 30MHz 18.6dB; 50MHz 15.0dB. (Recall that 14dB RL = 1.5:1 VSWR.)

IMD--tones of 3 and 4 MHz were used, set to 0dBm each at output of amp, to spectrum analyzer.
3IMD product at -77dBm = +38 OIP3 (products at 10,11,5,2 MHz)
2IMD product at -50dBm = +50 OIP2 (products at 7,1 MHz)

Max output power--amp was still linear at +20dBm single-tone output, at 3MHz.

Noise Figure tests--using information from various sources, notably Hayward's book "Introduction to RF Design", by measuring the MDS of a communications receiver, then determining its filter's noise bandwidth, the noise figure of the receiver alone can be determined. Then by cascading the amp with the receiver in series, the overall noise figure can be determined, and then the noise figure of the amp itself can be determined.
Hayward discusses noise bandwidth for a communications receiver using steep-skirted filters to be equivalent to the -6dB bandwidth of the filter. This is easily measured with a calibrated signal generator and an audio rms voltmeter connected to the receiver's audio output. Then the MDS (3dB increase in audio output) of the receiver and amp/receiver combination is measured, and the values plugged into the formulas to derive the various noise figures.
My receiver, an AR-7030, with internal preamp off, in CW mode with narrowest filter selected (500Hz--measured -6dB bandwidth of 570Hz) had an MDS of -127dBm, to give a noise figure of 19.4dB.
Amp and receiver together had an MDS of about -136.7 dBm, for an overall noise figure of 9.7dB.
(All noise figure tests were done at 450kHz, mainly because I'm interested in a low-NF LF amplifier.)
Substituting values in the cascade noise figure equation to solve for the amp's noise figure, using Fnet = 9.7dB; F2 = 19.4dB; G1 = 10.5dB, gives a value for F1, the amp, as 2.2dB noise figure. (I have the hardest time remembering that all values in the cascade NF equation are not dB's but algebraic numbers, and then converting the final result back to dB for the final NF value.)
So, the amp has a respectable low noise figure at 450kHz.

Overall, this is a pretty decent amp. I should substitute a common 2N5109 and redo the noise figure measurement, but I don't expect the results to change much. The datasheet for the MRF586 doesn't indicate a very low NF for this device. Perhaps the best features of the amp are its very good input and output return loss (VSWR) values and its good reverse isolation. Having a low noise figure and good low frequency response, along with decent IMD performance, doesn't hurt, either! And no additional "bandaids", such as ferrite beads, were needed to tame any instabilities.
If you're looking for a decent-performing amp, you might want to get a copy of the article and breadboard the circuit, and give it a try.

(If you're unable to find this article, I could be persuaded to mail a copy, for postage and copying costs. Note that 4 patents are listed, pertaining to this amp, if you have thoughts of making this amp available for sale commercially.)

Try going to http://qrp.lehigh.edu/lists/qrp-l/, subscribe to the reflector for just a few days, then ask that question.

Or like Ken said, go to Dayton, then ask that question.

The numbers are down, no doubt. But dying out is a little strong. I would say there certainly seems to be more interest in homebrewing than 10 years ago. Could be just that the Internet brings more homebrewers/kit builders together. Certainly it makes parts easier to get and gives kit suppliers easier access to their market.

BTW, as nice as an SB-102 is, newer kits can run circles around it at a fraction of the price. Nowadays, when you buy a Heathkit you are buying an antique, and paying antique collector prices for it. If you could find a NIB 102, I'll bet it will fetch a couple of grand. Seems like a few months back an unbuilt HW-7 fetched about $800 ... this is a radio worth less than $50 built.

If you really want to melt solder, take a peek at the stuff from Elecraft, NorCal, Small Wonder Labs, OHR, Red Hot Radio, etc. etc. etc. Then look at Homebrew stuff from K8IQY, NJQRP, Harry's Homebrew Homepage, EI9GQ, etc. etc. In fact, if you go to QRP ARCI's links page, they must have a list of 50 kit suppliers. You won't get the nice feeling of building an old Heathkit (if you can stand to put it together after seeing the price), but you will get a nicer rig for a bunch less money.

I sold a partially built Heath audio spectrum analyzer for $400 on the Bay a couple years ago. it had collected dust here since 1985. I also sold a rebuilt Dynaco ST70 for over $500 -- the Audio Research modification -- I asked the guy 3 times if he was sure he wanted to pay that much. I felt so guilty I gave the proceeds to an inner city school I do some work for. Lastly, some guy in Taiwan paid $113 for a Leader distortion meter, it cost a fortune to ship. You can buy a used HP334 for almost as much.

While it is nice to play with circuits do you have any idea how it will
compair to one of the MMICS ? Something like a mar6.
Most of the work has been done internal so all you need is a couple of
isolating capacitors and one resistor.

> and get on the wir with it. I'm KW0WW BTW.

Being a certified solderer was never a prerequisite for putting together a Heathkit. The 1 or 2 pages on "How To Solder", in all of the Heath manuals, was usually enough for anyone to put one together and get them running. Although my first kit, at the tender age of 10, was a Knight Kit Star Roamer I have built, used, and still use many Heathkits. They made good units and are easy to fix, but that may be because I grew up with them and have had 40 years to understand them. I have a SB-101 on my workbench right now with a keying delay problem. I know what the problem is, I'm just waiting on the replacement tube.

IMHO, buying a unbuilt Heathkit for the purposes of building it would be a huge waste of money. You would pay several thousand dollars for a unbuilt SB-102 and, the second you put a soldering iron to the first wire the worth would drop to less than 5% of what you paid. Putting together one of the newer kits, as opposed to a Heathkit, is no less satisfying and you don't run into the huge investment loss.

An advantage of a newer kit is that it is going to be designed with a newer technology. Something that may be easier to understand than taking a trip in the "wayback" machine and learning about tubes. And the newer kit will work as good, if not better, than a Heathkit. The money you save can then be spent on other goodies, like a nice shiny new CW key. :)

My Heathkits include, but are not limited to: Twoer, Sixer, DX-40, SB-10, HO-10, HR-1680, HX-1681, HM-102, HM-2102, ...
I love then all and still use them all, but I would like a kit made by someone else just as much.

Ok, then can I actually build a full featured all band HF transceiver that
will stand up against the Asian assembled ones they sell retail?

One of Heathkit's original failings was that, for the same money, you
couldn't build a rig with anything near the features of a commercially made
ones.

BTW, it sounds interesting, but I'm not really into QRP. Is anyone making a
full featured all band HF transceiver kit that puts out full power? (like
100-200 watts PEP out?)

Hi Ralph,
There is little comparison between a MMIC and a discrete amp. Only noise figure might be similar. The discrete amp will almost always be superior in terms of overload resistance, and most of the other parameters I tested.
Makers of amps for the hobby market, such as Kiwa, Wellbrook, Advanced Receiver Research continue to sell their products, when MMICs are readily available.
If your only interest in a preamp is sensitivity, and you don't care about any of the other parameters, and you plan to use the amp in a very-rural area, far from any sort of potential overload problem (transmitters), then perhaps a simple MMIC circuit might be the best/easiest solution.
Steve

A good discrete circuit can probably outperform an excellent mmic,
but there are some damned good mmics out there. For example, take
a look at the Stanford SGA-4586 or the SGA-6X89... They can put out
between 10 and 100mw (depending on unit), and have somewhere between
1.8 and 3dB NF. They are also made up from SiGe, therefore doing
better on the low end (NF) than PHEMT fets.

There is indeed an issue of input/output isolation when using most
mmics, but there are some parts that have lesser specs in some areas,
but also provide much better input/output isolation.

Hi All;
I have for Sale a working EV664 microphone, comes with connector & healthy length of cable.
Condition is real nice overall, some minor pitting on the sides id the same area shown in pic #2.
Price is $160ppd Conus.

Bill,

It all depends on how the crystal was cut. Some are more pullable than others.

A crystal may be modeled by an RLC circuit in parallel with a very small (like 7pF) capacitor in parallel.

If I understand correctly, the larger the C in the RLC and smaller load capacitors and parasitic capacitors will yield a more pullable crystal.

Buy some crystals and try it!

Steve,

I have had good luck with Advanced Circuits in Colorado. They did 2 protos for $33 each, plus shipping. 2 layer. I think they will go up to 30 square inches at that price.

You can always go to the swap meet and pick one up and RE-build It...
That's how I got mine in '76. Most of the parts are easily replaced
by generics and through original manufacturers. The dial parts and
the drive belts are the biggest problem. I suspect the drive belts could
be found in vacuum cleaner shops or from PRB (tape/vcr/projector
belt jobber).

2306. The transformer in a noise bridge circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-22 05:24:40 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203212124.21d541f9@posting.google.com>
Source record: 45396
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

As I mentioned before, I would like to build a modified version of the SWR noise bridge shown on page 27-25 of _The ARRL Antenna Book_. The schematic is available at http://www.qsl.net/wq1rp/noisebrg.htm, as the New England QRP group sells a kit.

I should note that my version of the noise bridge will be an improved version of the MFJ-212 Matchmaker (http://www.mfjenterprises.com/products.php?prodid=MFJ-212). Please note that the MFJ-212 does NOT have the resistance or reactance dial, and my noise bridge will not either.

The NE555P chip interacts with the diodes and resistor to produce an output voltage that consists of a 1000 Hz square wave. When it interacts with the Zener diode, a broadband RF noise source is produced. The 2N2222A BJTs amplify the RF white noise signal.

Exactly what does the transformer and the rest of the circuit do? My general understanding is that the transformer sends the RF noise into the transmission line. Since there turns ratio is 1:1, the voltage and current ratios are 1:1. The RF noise is sent towards the antenna through the coaxial cable. Any mismatch between the coax and antenna results in reflected RF voltage, which propagates towards the receiver. The larger the reflected RF noise signal, the louder the noise you hear. Adjusting the resistance and reactance dials for the minimum noise reveals the feedpoint impedance.

Some questions:
1. What do the 82 microfarad and 47 microfarad capacitors between the transformer and antenna do? Are they part of an SWR bridge circuit?
2. When the RF voltage returns to the noise bridge, what prevents the transformer from coupling the RF back to where it originated? Or is it stopped at the back end of the last amplifier? (Sorry, I haven't studied transformers in 8 years and never really understood them in the first place.)
3. How would I modify the noise bridge to (gasp!) omit the resistance and reactance dials? Some of you might say that this circuit would no longer be a noise bridge, but the MFJ-212 lacks those dials. I simply want to send the RF noise to the receiver so that I can adjust the antenna and tuner for minimum noise (a byproduct of minimum SWR).
4. Where can I buy an Amidon BLN-43-2402 ferrite binocular core? What acceptable substitutes are there?

Hehe, I was gonna suggest that too but I figured it was a 'bad' answer
and I'd get flamed. Refurbing an old set can provide many more 'hobby
hours' as opposed to simply opening the can and serving the dish.

>compair to one of the MMICS ? Something like a mar6.

MAR-6 is the worst device for HF preamplification, unless you have a
very narrow front end. The gain is very high and output very low, so
it will saturate at quite low input levels. It is however, very usable
for LF/MF indoor loops, which are quite selective but produce a very
low output.

However, MMICs like MAV-11 have output power and output IP3 points a
few dBs below those of the 1989 RF Design specifications with similar
gain figures.

If you are going to wind transformers, why not put two MAV-11s in push
pull and get similar specifications as the 1989 design.

Hi Folks,
I would like to convert a 14Mhz Class C RF amp to 7Mhz
the circuit is here..

www.corn2.freeserve.co.uk\25wrfamp.gif

My knowledge of RF amps is almost nil, so I know enough to know I need
help here.
I believe the input and interstage is broadband but the output is a
frequency specific 'T' matching network, but I'm not sure.
If someone could guide me on this one I'd appreciate it.

thanks Mike W

The Elecraft K2 in base configuration is a QRP rig. Well, close to it.
Mine
puts out almost 15W on some bands, although I never use it over 10W. It
can be built to 'fine tune' it to closer to 5W max if you're really serious
about
QRP. If you build it that way, it's slightly more frugal with the battery
than
it is if you 'turn it down' to 5W.

But if you're not into QRP, there is an optional kit to make it a QRO rig.
At one time they were talking about a 50W or a 100W option.

I know they've tested it, but I don't recall if it's offered for sale yet.
Obviously not a battery power rig anymore. In fact, you have to give up
the 'top panel' options for it. That means no internal battery and no ATU.
But the ATU is for 20W max anyway.

Now, who knows if the optional QRO will ever finally make it out, but
the rig is a nice piece of work even as is. And if you want to build QRO,
build an amp for it. There's already kits (or at least, parts list as
'pseudo-
kits' what with the FCC rules to prevent abuse on 11M) for amps on the
market for the K2 and 817 that are attuned to the fact it's a QRP rig.

I thought about an outboard amp at home for mine, but it just seems I'm
not having too much trouble with just 10W.

Stephen
We have got to the PCB stage for the DDS/PLL synthesizer. This would be suitable for a wideband receiver LO if the performnace is as good as we think
Resolution could be 1 Hz or better if required from 1-2 GHz. By substituting different PLL chips and VCO modules (all should be pin compatible) itr should be possible to cover a wide frequency range from 100 MHz up. John Miles should have a prototype built in a couple of weeks.We will keep you posted.

OK, the K2 I believe is now available with the 100W option.

As far as I can tell, none of the kits have all the features of the rice boxes, depending on what features you care about. The K2 trades off some of the frills of the mid range commercial rigs to get top of the line receiver performance. There are a number of K2 features not found in the commercial rigs, but they tend to be features of interest to QRPers. A fully decked-out K2 is comparable in price to a mid-range commercial rig. The receiver specs are more comparable to a Japanese rig three times the price.

(oh yeah, the obvious URL http://www.elecraft.com, also see the reviews at the Adventure Radio Society site and QST. ARS has some nice comparative data).

I happen to have a K1, which is a much more limited rig than the K2 (and a much more limited price!) What struck me is the ergonomics. The rig is much better laid out than my Icom. In spite of being a low-end rig, the thing is a joy to use.

It's a little hard to get objective feedback on the K2. People who have them are absolutely rabid about the things. I would suggest finding someone who has one and playing with it a bit. In my opinion, it's a nice rig, and I have played with a couple. But you're not going to learn anything from talking to someone who has one ... they are all blinded by the Elecraft mojo.

..

Well, I take that back. People on the Elecraft reflector are talking like they have the 100W option, but I see no trace of it on the web site. (Since I'm not a QROer, I have to admit blowing by all those notes about the amp anyway).

k5oor's first build of his HF Packer amp is closed, next build likely not until the end of the year (http://www.hfprojects.com)

Also, I would suggest downloading the construction manual. Heathkit never made a manual as good as Elecraft's.

>Exactly what does the transformer and the rest of the circuit do?

This is the point of my suggesting YOU determine the minimum circuit
configuration of a bridge. Jason, you should start doing your own
homework by now and explaining to US how it works to both confirm your
understanding and become an active rather than passive participant.

>
>Some questions:
>1. What do the 82 microfarad and 47 microfarad capacitors between the
>transformer and antenna do? Are they part of an SWR bridge circuit?

There are only six (6) capacitors shown, none more than 0.01 ï¿½Fd. You
need to answer more questions than ask them at this point.

>2. When the RF voltage returns to the noise bridge, what prevents the
>transformer from coupling the RF back to where it originated?

Nothing - the consequences doesn't matter either. It is enough to
accept that it does couple back (the whole point of an imbalance).

>Or is it
>stopped at the back end of the last amplifier? (Sorry, I haven't
>studied transformers in 8 years and never really understood them in
>the first place.)

Understanding the minutia of transformers is wholly unnecessary, they
can be treated as black boxes if first you accept their principle
application of isolation and balance. Do you grasp the operational
necessities of the simple DC Wheatstone Bridge? No transformers there
to cloud the issue, and everything works the same as the noise bridge.
Visit the engineering section in a library at a community college for
an hour.

>3. How would I modify the noise bridge to (gasp!) omit the resistance
>and reactance dials? Some of you might say that this circuit would no
>longer be a noise bridge, but the MFJ-212 lacks those dials.

The facetious reply would be to peel off the labels and remove the
knobs.

Omitting the components would render it useless - unless you just want to listen to noise for no purpose.

>I simply
>want to send the RF noise to the receiver so that I can adjust the
>antenna and tuner for minimum noise (a byproduct of minimum SWR).

That won't happen in the direction you are moving.

>4. Where can I buy an Amidon BLN-43-2402 ferrite binocular core? What

>Jason Hsu, AG4DG

Hi Jason,

I would have offered:
http://www.bytemark.com
as a source, but they seem intent on commercial suicide over the net by taking down working pages to replace them with the announcement of a new site being built. As alta vista revealed 515 references to the query "amidon ferrite" you could as easily find another vendor one would think.

I don't know why you are looking into binocular cores, but that is a move in the right direction; however, do you have a good reason (the right one that is)? Given your professed ignorance of transformers, you are in over your head to make changes in circuit design in advance of actually building a working, original model.

2318. Re: The transformer in a noise bridge circuit

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-22 19:11:43 UTC
From: k7itm@aol.com
Message-ID: <3200347.0203221111.47141b98@posting.google.com>
Source record: 45409
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

The transformer is an integral part of the bridge. To get zero going
to the receiver, the voltage at the top end and at the bottom end of
the transformer must be 180 degrees out of phase and equal magnitude.
That happens if the net impedance load on each end of the transformer
to common is the same. -- I'm not sure what schematic you're looking
at...I have the noisebrg.htm schematic up, and it shows only a 27pF
cap feeding the antenna from the transformer. If the "unknown" is
then 50 ohms, you get balance with a 27pF capacitance on the variable
and a 50 ohm setting of the variable. If you want to omit the
variables, just use a 50 ohm fixed on the top end and replace the
variable cap with a short circuit; on the bottom end you could omit
the cap (replace with a short) or use, say, a tiny 0.01uF cap to block
DC (dunno why you'd need it, though).

You should be able to get an Amidon part from Amidon Associates,
though when I visited their web site recently it looked like they are
discouraging direct purchase of small quantities. Do a Google search
for Amidon and you'll turn up other sources.

Cheers,
Tom

I'm personally just interested in a nice stable multimode rig (except
maybe CW which I think is obsolete anyway and should no longer be required
for licensing) with a digital readout and perhaps a spectrum display, that
will cover all bands. SWL bands would be nice too, and if I could afford
one, it would also have complete receiver coverage from 100Hz to maybe 1 or
2 GHz. I may need a rice box for all that, I don't know. But if I start
wishing and fantasizing, there it goes, from an SB102 to all that. :)

Hello - Have for sale these parts :
Mini-Circuits MAR-1 MMIC's in sealed bubble packs, have around 7 strips
to sell. Each strip is 10 MMIC's and cost is 17.50 per strip of 10.
Philips Dual Gate MOSFET device BF-980, this is a low noise VHF-UHF DG
MOSFET in the "X" package. These are very handy and supplies are drying up,
stock up now. These are NOS in static bags.
Pkg. of 50, 3 to sell at 35.00 each
Pkg. of 25, 4 to sell at 20.00 each

Thanks, WA5THJ.

2323. Re: Radiation from monitors

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-22 22:27:46 UTC
From: AB Brown <abbrown@nospammail.com>
Message-ID: <a7gbenemj1@slb4.atl.mindspring.net>
Source record: 45412

For what it's worth, I've been studying low level radiation sources for years. As for computer or television CRT's, most of the x-radiation used to come from the high voltage regulation circuits (flyback circuits), which used vacuum tube diodes/ regulators. Since these vacuum tube circuits would operate with up to 40 Kv sources, weak x-rays could be produced that could easily penetrate the tv chassis and cabinet. People sitting near the tv would be exposed over long periods of time. However, the time period we're talking about here is the 1970's and earlier sets, before stricter regulations were in effect.

In my x-radiation detection experiments of early (pre-1980's) CRT's, the only way I could detect x-rays was with a scintillation counter especially made for x-ray detection. Even then, radiation levels produced were just barely above background. CRT's obviously did produce some x-rays, but the real danger lied in the tv flyback circuits described above.

I'd say that greater than 99 percent of todays CRT's, both television and computer type, use solid state flyback circuits. Instead of a tube regulation circuit, transistors are used thereby eliminating x-ray production from these circuits. The CRT's often use lead glass and filter out all but the weakest rays, which wouldn't even penetrate the skin anyway. That's not to say that a malfunction in the voltage feeding the CRT wouldn't possibly increase x-ray production as it could, but the possibility is very remote.

Using film as you have is one of the best, and cheapest, ways to detect x-rays. However, if you really want to know your exposure, a program of dosimetery is better. You wear a special badge anytime you're near the CRT, or whatever device you suspect, and every quarter (3 months), you mail off the badge to a firm that uses special instrumentation to determine how much radiation you've received. A dosimetery program is very good for determining exposure received, but it is also very expensive.

One must remember that x-rays are simply electromagnetic radiation, just like radio waves but of a much shorter wavelength. They are really low energy gamma rays. They can damage biological organisms just like other forms of radiation. When exposed to high levels, the damage shows up in a short period of time i.e. radiation sickness. Then there are delayed effects, those that don't appear for years after exposure, like cancer. These delayed effects usually result from lower exposures over a much longer period of time i.e. sleeping next to a wall covered with uranium glazed pottery for 50 years.

Over the millenia, the human body has developed certain defense mechanisms for radiation. The level of protection depends on health, genetics, and environment to name just a few.

So, would I be concerned with the radiation coming from my monitor? Yes, if tests revealed abnormal operation and large amounts of x-radiation being released. No, if the monitor was operating within normal limits and I used common sense to avoid excessive exposure, like maintaining a safe distance for one.

I know I've gone a little overboard here, but I hope you find this information useful.

What are the crystals that allow the greatest frequency pulling?
HC-49, HC-33
and HC-6 are some of the xtal types I see for ordering. Any of those
better than the others??

Thanks,

Bill

Old HC6/U and FT-243 types are supposed to be best for series mode pull, while computer type and colour burst xtals seems to give best results for parallel mode, you may also specify 'rubber type' xtals which are used for frequency modulation on 9, 10.7MHz or other

Mike, this is an easy one. You need to simply scale the folloeing components.L3, L4, L5, The 200pF and the 450pF caps.

To go from 14 to 7mHz you must have the same reactance of these components at 7MHz as they now do at 14MHz. OK this means doubling the value of L3, L4, and L5. You also need to do the same for the same thing with the capacitors mentioned above. I am assuming that the rest of the amplifier is broad banded and that the reactances of the transformers is sufficient at 7MHz. ther is no way i can varify this from your circuit. I would just assume it is OK. You can always ask for help again if required later.

Dear AB Brown (and all others who took part in this topic),

No, you haven't gone too far - I think that the topic deserves a
complete analysis. Your post has been most informative for me. Thanks.
Now, several answers on this news group have persuaded me that the
danger of monitor radiation is not very great, but it still exists.
Another post said that LCD screens are coming as a definite solution.
But that process is very slow. Anyhow, I have learned something more.
Thank you.

Just another item to look at....

In addition to scaling the matching network components, you need to examine
any
bypass or blocking components (bypass caps, RF chokes, etc) used in the
circuit.

The values used may be inadequate for 7 Mhz operation and if so, they would
need to be scaled for the new frequency of operation also.

I have tried the Circuitmaker student version, which I have found to be one of the best, but unfortunately it does not include a " simple layout program", at least the one I downloaded. There is a so called "demo" version that can be used for a month that has the autrouter included, but I have found it not to be of much use for simple circuits, it's great for complex circuits. Ideally a stand-alone router or layout program would be what I would be most interested in using.

Other then being blue, what was special about the arcuturus tubes of the 20's ?

2337. Sizing blowers for external anode tubes (anyone good with fluid mechanics?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-24 00:08:17 UTC
From: tongaloa <tongaloa@alltel.net>
Message-ID: <a7j5di$2na$1@iac5.navix.net>
Source record: 45426

I've a surplus Soviet Military vacuum tube.
It requires forced air cooling of 40 m**3/hour
(I'm assuming this is at STP so 52kg/hour and
specific heat capacity is about 1000 J/deg K)
in order to remove 350W from the heat exchanger.
The 18 'holes' in the heat exchanger have a cross section
totaling 200 mm**3

Here are some drawings of the tube/valve.
http://www.nd2x.net/gi7b.html
these are radial view.
If one makes an axial view there are
18 little pie slices (triangles) and the area of these
sums to 200 mm**2

40 m**3 per hour is 200 km/h of uncompressed axial flow!
As an aside, I'd be curious as to how much noise to expect...

Blowers are specified in terms of volume for a given
back pressure. i.e. 40 m**3 at 5 cm(water)
So, what I need to know is...
How the heck do I figure out the pressure drop
in squeezing 40 m**3 per hour of air through this thing.

I'll be sizing the blower to work wt 100 degrees F ambient at sea level.

2338. Bandswitch & Tune Cap For Sale

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-24 00:44:01 UTC
From: Jeff Weinberg W8CQ <w8cqjeff@tds.net>
Message-ID: <lj9n8.19578$IN3.6444288@kent.svc.tds.net>
Source record: 45427
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap

Hi All,
I have the following for sale:

1 - Multitech Industries Model 86A Custom Bandswitch. This is a switch I had made for an amp project and no longer need it. It was never used or soldered on. It is very similar to the nice switches in the QRO and Commander amplifiers. It has 2 sections (1 for tank/tune cap padder switching, the other for load cap padder switching). It is set up for 160-10 meter operation. A technical drawing of the switch is also listed in the links. I have over $200 in the switch. I would sell it for $150, shipping included.

Pictures and the tech sheet can be seen at the following links:
http://www.harbachelectronics.com/forsale/switch1.jpg
http://www.harbachelectronics.com/forsale/switch2.jpg
http://www.harbachelectronics.com/forsale/switchdwg.jpg

1- EF Johnson Tune Capacitor. Specs are ~240pF at 7KV (0.175" plate spacing). The cap is used, but does not have arc marks or burns. The dimensions are approximately 12" long x 5" wide x 5" tall. This would make a great tune cap for a homebrew. I would like $40 for it, shipping included.

A picture of the capacitor is at:
http://www.harbachelectronics.com/forsale/tunecap.jpg

It appears you are confusing cubic meters of air with velocity.

A cubic meter is approx 35 cubic feet, so that is something like 1400 cubic feet per hour of air flow, which is fairly slow air exchange.

I just looked at industrial blowers on the web and they were speced at 28-4600 cmm, that is per minute, your spec is .66cmm.
thanks, John.

I would try Eagle. It is free, and has no limitations, except:

1: The board size
2: 2 layers.

Other than that, it is fully functional, and has auto route capability,
and they have just came out with an updated version.

What is the maximum allowed heat exchanger temperature ?

It appears that you are using 25 K as the air temperature increase to
remove 350 W of power (0.0144 kg/s * 1 KJ/kg/K * 25 K = 0.36 kW).

A 25 K temperature increase sounds about right for a germanium power
transistor :-), but for a tube amplifier with 40 C inlet temperature,
a 140 C (or more) outlet temperature sounds more likely, corresponding
to a 100 K temperature increase and thus, a required air flow of 10
m**3/hour (or less).

Paul-
This is useful.
The max seal temp is 200C
The manufacturer states 40m**3/hour for 350W.
I did a calc of the outlet temperature based on the
mass flow and the specific heat capacity of air at STP.
This doesn't tell me the temp difference between the
air and the heat exchanger. The heat exchanger is rather
small.

Hi,

I have a Jennings vacuum variable capacitor for sale.
The capacitor is a UCSX 1000, which is a 25-1000 pf 15kv
vacuum variable. The cap has the puller with a .5" shaft diameter.

The prices is $70 plus shipping. I can email a picture of the
cap if interested.

Please remove the xyz from my email address if you care to respond.

Thanks,

Jack

2351. Re: Sizing blowers for external anode tubes (anyone good with fluid mechanics?)

From: tongaloa <tongaloa@alltel.net>
Message-ID: <a7l194$7dr$1@iac5.navix.net>
Source record: 45443

My math is correct(see near end),
but that's not the point.

I need the back pressure or head
if I'm to size a blower.

Flow is resisted by a pressure increase. Pressure increase
is a result of the force required to overcome the friction
of the heat exchanger plus the increase that results from
heat conducted from the exchanger.

Blowers are specified in volume/(unit time * head).
So I have to know the head in order to choose a blower.

-bob

If I'm sending 40m**3 through a 200mm**2
hole and assume no compression, then
40m**3 per hour/0.0002m**2 cross section
gives 200000m/hour... (200km/hour)
In feet:
40m**3=24CFM
200mm**2=0.31in**2 or 0.00215ft**2
result is 11148 fpm = 2.1mpm = 127mph

Source record: 45445

Bozidar, you're welcome. The earlier post was correct about LCD monitors, they will not produce x-rays. Why?

Because, in order for x-rays to be produced, two things must be present: high voltage, on the order of at least 10 Kv, and high vacuum. Most vacuum tubes used in radio service have the high vacuum needed, but are seldom operated above 5 Kv, so no x-rays are produced. Many CRT tubes though operate at higher voltages, many times exceeding 10 Kv, so weak x-rays might be produced, especially in thin or non-leaded CRT tubes. Like I mentioned yesterday, there are much stricter regulations these days compared to 20+ years ago, so x-ray production, if any, would be barely discernable. The main hazard was in the flyback circuits that used tubes, many times being operated near 40 Kv. Today's are almost all solid state.

With LCD screens, there is neither high voltage nor high vacuum present so x-rays cannot be produced. LCD's use a completely different way of generating motion pictures than CRT's. In fact, I think that, once the technology is perfected, you'll see the near end of the CRT in the coming years. I say "near end" because there will still be certain applications where only a CRT can be used.

It is interesting to note that since x-rays are electromagnetic, just like radio and light waves, it would be possible to use them for communication purposes if one so desired. However, the harm greatly outweighs the benefits here, so I don't think anyone has tried it.

From: tongaloa <tongaloa@alltel.net>
Message-ID: <a7lclu$dk2$1@iac5.navix.net>
Source record: 45446

Paul-

I went back and looked at the operating parameters for the
tube/valve and the ambient temp range extends to 100C
with a maximum relative humidity of 98% at 40degrees C.

If the 40m**3 is specified at 100C then the density is 1kg/m**3 (77%),
the rate is 0.0111 kg/s, making the temp rise 31.5C and exit 131.5C
which is close to your 140C

I really don't have a feel for these numbers....

So, it looks like with 40 degree and 98% air humidity ambient
which is also about 1kg/m**3 Bottom line, I can reduce the
mass flow by 1/3 and my rise will be about 100C

I don't know the pressure drop squeezing 13m**2 through,
any more than I know it for 40m**3.
I've still got the problem of sizing the blower!!!
It is sounding smaller and less expensive.
With the velocity in the orifice down to 70km/hour
as a worst case, it will definitely be quieter as well.

Hello all,

My name is Patrick Cambre and I live in New Iberia, La., USA.

I like to go to different forums and post of my new website that has a fascinating little project on it. I call it the Radio Shack Special.

I have gotten many an e-mail, since I have been posting it and a lot of
people love to make these small simple projects.

Introducing to you...the one transistor FM receiver!

The sensitivity, selectivity and great audio output is what you will get from this marvalous little jewel! In fact, Radio Shack is waiting for you...I have designed this so as to get ALL of the parts from there....no need to wait on a mail order company.

I could tell you all about it here....but if you go to my website and sit back and read...you will see the complete plans on it....

I do want to say thank you very much for taking the time to read this article.

The Radio Shack Special is at: http://braincambre500.freeservers.com

When you get there...also read what 'Pedro' has to say about it....he also
made one...

...a friend, Patrick

2360. ATU for magnetic loop antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-25 13:41:16 UTC
From: Fabio Morsani <fabio.morsani@pi.infn.it>
Message-ID: <3C9F28FC.D98F5DEC@pi.infn.it>
Source record: 45302

I developed an automatic tuner for my homebrew magnetic loop antenna.
It allows the user to directly enter the desired freq using a 4x4
keyboard, then the ATU tunes the loop at that freq for minimum SWR.
Alternatively (preferred), you can just press a key and the ATU reads
automatically the current RTX freq (for my TS130, it reads the local
oscillator freq and subtract the IF value) then performs the tuning.
More, the keyer and the mic pass through the ATU, which allows the
PTT (used for CW also) to be asserted to the RTX only if the current
SWR is below a programmed limit ... and other features.

I successfully used such a ATU for some years.
Recently I developed a serial interface to connect the ATU to
the CAT port of some commercial RTXs (ICOM, FT1000, TS850 ...).

I'd like to know if someone has built something of similar, his
experience, some ideas to improve it.

On my site http://dai5lhy.dadacasa.supereva.it/
you can find some info (for the moment in italian only).

I don't have data-sheets for either device but IIRC, the
2SK19 in an n-channel JFET and the 2SC373 is an NPN
transistor. Every amateur shack should have a stock
of general-purpose transistors.

Popular JFET's: 2N3819, MPF102, BF256......

Transistors NPN: BC548, 2N2222, PN2222.....

Source record: 45312

Greetings!

I am attempting to measure current using a 50mV shunt. The current can be moving in either direction. Clearly I can use an instrumentation amp with dual-rail power supply, but this would be the only need for a negative voltage in my system. Does anyone know of a cleaver way to do this using a single rail supply? A charge-pump chip to generate the negative supply is about a $2.00 part, so if cleaver>$2.00 then I'll stick to the dual-rails.

Thanks,
doug

I don't have data sheets, but if these are like other power modules I'm
familiar with, they may be designed to work in a specific frequency range
and will not be appropriate for use in the HF band.

Bill, I would guess that these modules are intended for the
High-VHF/UHF bands. When you get down to DC (relativly speaking, ie
28Mhz and below) they will do nothing useful.
But I could be wrong, I usually am.

Source record: 45316

I would like to start an rf test equipment operation course training. From reading online forums, I know many others are interested in this type of training. However, getting people together to organize this is a challenge. Also, the cost of the equipment is expensive

Very few colleges offer rf courses and it is hard to get the courses. Also, you have to wait a whole school term if you miss this current class. Even when a class is offered, it does not have the training with useful content. The topice is presented academically and it is hard to put this knowledge to use. Some private training companies DO offer this training. However, they offer "short courses" for 2-5 days. Also, they charge something like $1500 per week, and not all of this is lab time. I believe, if I got some people together, the course can be done less expensively, and there would be more lab time and more training in this area.

I am in the MA/ Southern NH area. Anyone in this area interested in such training? I would like the format to be a combination of equipment usage and technical discussions. Do not hesitate to contact me if you are interested in rf test equipment operation. My email address is vshah101@aol.com. If you have some suggestions or comments, please reply in this forum.

Also, I am interested in getting people together and sharing their design project experience. This a good way to learn more about rf.

Source record: 45317

Well, if the voltage across your 50mV shunt doesn't go beyond about 50mV, there should be no reason you can't do it with a simple op amp circuit. Just pick an op amp whose input common mode range extends to the negative rail, and 50 millivolts beyond (or however far your shunt will take it). Connect the amplifier in a standard inverting configuration across the shunt: that would result in the op amp output going both + and -, and of course it can't go -. So to solve that problem, bias the op amp + input up just a bit, using a resistive divider from a reference voltage.

In fact, if you use a resistor R from each op amp input to the two sides of the shunt, and a resistor n*R from op amp (-) input to op amp output, and a resistor also n*R from V-reference to op amp (+) input, then the op amp output will be referenced to the V-reference voltage. It's just the "output" stage of a standard three-amplifier instrumentation amp, set up for a gain of n. You don't need the input stages, because your source is a very low impedance to begin with. Furthermore, biased like this, the op amp inputs never need to go negative. You just have to deal with an output voltage as a difference from the reference voltage. (Note: if you're running an ADC from a reference and the ADC FS = the reference voltage, you can make that second n*R actually two 2*n*R resistors, one to common and one to Vref, and then the output of the op amp is centered on Vref/2.)

BTW, I'm doing just this sort of thing in a circuit (some of my charity work) to monitor power line VOLTAGE to the tune of 350 volts peak above and below the rail...and of course my "n" is actually about 0.006 so I get a nominally 4V p-p signal, centered on +2.5V, to digitize with a PIC16C73 or similar. The differential nature of the input means that my output side common isn't connected to either side of the input...there's over a megohm of isolation (the input resistors). It just couldn't accomodate a line voltage that was offset too far from the output common.

(How much money does that save you? Do I get a commission?)

Cheers,
Tom

Does your radio have an S meter?

You could build a simple op-amp circuit that senses the current in the S meter circuit.

Another way would be to tap into the AGC circuitry. Most commercial receivers now have some form of AGC. This might work better than using the S meter. I would suggest a high input impedance op-amp buffer followed by a schmitt trigger circuit.

To go beyond these general comments we would have to know the details of your receiver circuitry.

Have you considered using a chip designed for this purpose? There are single rail chips that can measure bi-directional curent. It provides a unipolar output with a current direction signal. Have a look at something like the Maxim MAX471 with built in sense resistor or the MAX472 which uses an external sense resistor.

regards,
Mark.

The easy way is to use a bridge rectifier with the shunt between the +
and - terminals and the AC terminals to the circuit to be measured.
Yes, you do have some offset but you only need a single rail.

Albert, there is a little circuit that Ten Tec offers which is the
Smart Squelch circuit #1064 and is a T-Kit.

Another thing I have done is parallel a small relay with the
speaker output to give a dry contact closure. This works
well with FM, but I am not sure what kind/type of radio you are
working with and what kind of mode, ie FM, SSB, CW etc.

What you're looking for is also known as a carrier operated relay or a COR signal.

Is this for FM and does the radio have a squelch control? If so, look at the schematic and track down the squelch section. For that matter, you could probably poke around that area with a meter while turning the squelch up and down.

2385. Triodes

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-27 04:09:40 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a7rgop$njos3$1@ID-124126.news.dfncis.de>
Source record: 45326

NOW AVAILABLE:

New Program, albeit belated, "TRIODE1.exe"

Program TRIODE1 assists with the design of triode, grounded-cathode, RF power amplifiers from 1 watt to any arbitrary large RF output power. For "anode" Americans can read "plate". For "tube" much of the English-speaking world can read "valve". (For grounded grids another program is needed.)

Tube operating conditions can be selected at 1 degree intervals from Class-A, via Class-AB1 and Class-AB2, to Class-C. In other words from anode current operating angles from 360 degrees down to very high conversion efficiency at 45 degrees.

The program first accepts a manufacturer's basic tube data: Mu = Amplification factor, Perveance which is related to cathode electron emission and equivalent conductance, and alpha, a value which defines the curvature in a tube's current-vs-voltage characteristics. The fraction of cathode current intercepted by the grid, sometimes neglected, is also taken into account. But if one or two parameters are unavailable all is not lost.

The program user can then enter his own operating conditions such as DC anode supply volts, amplitude of grid and anode RF voltages, intrinsic Q of the tank coil, output circuit operating Q and, of course, anode current operating angle and operating frequency. Operating angle is a little known but vital factor which a circuit designer must not neglect. It profoundly effects circuit operation by controlling a tube's internal resistance.

It may not go unnoticed there is no reference in the program as to what the internal resistance of a tube might be. Or to matching an amplifier's internal resistance to its load for the purpose of maximising power delivered to that load.

Computed output data includes DC anode current, DC power input, anode dissipation, conversion efficiency, DC grid current, DC grid bias, grid bias resistor value, grid operating angle, grid dissipation, and grid RF drive power required to satisfy the assumed operating conditions. (A common design

feature not covered by the program is deliberate dissipation of RF drive power in a damping resistor to improve operating stability. However this does not effect basic circuit design.)

The output circuit may be either a simple tuned tank circuit with a link coupling to a 50-ohm load, or a Pi-matching circuit. All coil and capacitor component values are computed. It is left to the designer to take parasitic tube and circuit capacitance and inductance into account. For coil dimensions, number of turns etc., refer to program SOLNOID2.

If a user should be unfamiliar with the characteristics of triode electron tubes this program will be found to be of educational value. By hitting one or another key the essential data for two types of tube can be entered ready for experimenting. But a set of anode/grid currents versus anode/grid voltage characteristics of any triode tube is essential.

There is a brief introductory note on each parameter used in the program. It may be of passing interest the basic mathematics are equally applicable to that much later 3-terminal amplifying device - the transistor.

On the other hand, for people who prefer the simple life, program TRIODE1.exe can be used just to calculate L and C values of a Pi-matching network to be used with a 3-500Z or any other power amplifier.

If Terman, Everitt, et-al had had this program available in the 1930's they would have got along much faster. ;o)

Download TRIODE1 from website below in a few seconds. One self-contained binary file only. Not zipped up. No unzipping inconvenience. Run immediately. All in plain English. Old timers can find out where they went wrong.

I didn't find the SAU64, but the M67754 lists the max bandwidth as
810-860 MHz. It won't work at HF and I doubt the other one will as
well. The lowest freq. range I found for these brick modules is 50-54
MHz. Take a look at http://www.rfparts.com/module.html

I'm not saying there aren't modules out there that are made for HF, but
I haven't seen any indication of it.

>
> Used to be that one used Terman. Found some computer programs on
> the net, but obscure.
==========

Have you tried program "T_TUNER" ?

Yes, many tuners fail around 30 MHz. This is *always* because of internal parasitic capacitance and and inductance associated with physically large components needed below at 14 MHz and below. An actual tuner circuit at 30 MHz is far more complicated than what can be seen by eye. Unseen extra bits of L and C occur all over the place.

The *only* solution is to construct a physically small tuner for 14 or 21 MHz and upwards. Enclose it in a very small box and keep all wiring down to an absolute minimum. The inconvenience of having to change tuners for the higher frquency bands just has to be lived with. It can be done with coax switches but they introduce their own very similar problems.

I don't think there's much to choose between T and Pi networks. If you are interested only in one band like 10m, then an L-network may be all that's necessary. Switch along a small self-supporting coil plus one small variable capacitor. Maximum value of variable capacitors should be no more then needed. Use program SOLNOID2 to design self-supporting coils. 16 or 14 gauge enamelled copper magnet wire will do fine. It is easier to find than bare copper.

Don't even dream about roller inductors at 30 MHz !

Download programs from website below. Just get yourself in the right ball-park and you will probably be quicker just by winding a few turns and checking what happens. Worry about putting it in a box only after you've got it working.

Don't place undue confidence in your SWR meter. If the transmitter seems happy stop fixing it and have fun !

Since you already have the items and they didn't cost
you anything, you could apply power, waft a bit of RF
at them and see what happens. Since HF is so far removed
from 800 MHz the matching networks will behave as
(approximately) open or short circuits.

I've read in history books that ham radio was once an
experimental hobby.

2391. low freq PLL for jumpy FM carrier tracking?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-27 20:20:21 UTC
From: Jan Wagner <jwagner@cc.hut.fi>
Message-ID: <3CA22985.6A8D508B@cc.hut.fi>
Source record: 45333

Hi,

on the matter of Tesla coils, i.e. solenoid coils...

This question is kinda complicated, but, what PLL chip would you think could work for the following setup?

[short form of question: Are there any PLL chips for receiving FM transmissions for transmitters operating below 500 kHz? (yeah, kilohertz). With max carrier frequency deviations of 30kHz, but 20kHz typical? The carrier is modulated slowly, maybe 10kHz, but can jump some 10kHz suddenly.]

Long form:
I've an external user selectable frequency reference between 50kHz..500kHz in 1kHz steps. The reference should be injected into the PLL. It's similar to the tuning frequency / local oscillator.

The main purpose is to drive a multiresonant high-Q RLC tank circuit (Tesla coil) at its fundamental resonant frequency, which, by the nature of Tesla coils, drifts around quite horribly because there are streamers and high voltage arcs and other cool stuff (desired effect) happening which will load down the solenoid coil and also change it's self-capacitance => self-resonant freq changes.

To track that resonant freq, the VCO out-put 50% duty square wave signal applied to the tank and the current drawn by the tank should be in phase. That's the purpose of the PLL. Sooo... one of the PLL inputs is fixed: the user-specified frequency. The other two change in frequency, i.e. the actual VCO output frequency and feedback signal (ok they have the same freq always, but a different phase in out-of tune conditions).

Yeah and not only this but the lock and track ranges should be +-30kHz (at most) around the user-specified frequency, always. And as said, that freq can be between 50kHz..500kHz. So I've been breaking my head over how to accomplish this... Any ideas? Tips?

Pocket digital FM receivers use a PLL, maybe similar to MC145157, with programmeable dividers. That's ok at >80MHz, but not nice at 500kHz as fast tracking is required (yeah, 14-bit counter, counting 500kHz pulses to finally pass through will take AGES...)

I'm not so familiar with the different varieties of PLL chips and their special functions and doodads, so that's the reason for asking here...

many thanks,
- Jan

Radio Shack sells (or used to sell) a small gadget that you could hold up to a rotary phone and input dtmf tones, I have one that I keep with my pocket 2 meter rig, if I hold it up to the mic input, I can use it to bring up the autopatch and dial.

If I recall it was less than 10 dollars for a complete solution to my problem (rig without keypad) perhaps you could buy one and hack enough of it to meet your needs.
thanks, John.

One could always build in a bypass switch for the lowband tuner and the highband tuner (160-20 and 17-10, respectively) each, and just use the one needed. Bypass the lowband tuner for the highband stuff, and vice versa...

Just an idea.

...

Well, there are several PLL chips designed for relatively low
frequencies. Have a look at the NE56x series from Philips/Signetics,
and the CD4046/74HC4046/4096 chips.

(It does seem like what you really want is simply a power oscillator
which uses the resonance of the coil to determine frequency...but I
don't claim to know anything about Tesla coils.)

Cheers,
Tom

I am planning on building a simple mosfet class AB amp using two irf510 mosfets. I came across a design that uses a phase-reversal choke to feed the drains of the mosfets to provide the positive and negative to an output transformer that isn't center tapped. The choke/transformer uses 10 bifilar turn of #22 on 2 stacked ft-50-43 cores.

2401. FS: RS 242 WW2 German power triode

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-28 10:48:14 UTC
From: arnoldg@c2i.net
Message-ID: <3ca2f534.9044009@news1.c2i.net>
Source record: 45343

Hello,

I have several of this antique globe shape German triode in stock. It is directly heated, an European 4-pin base and about 12W anode dissipation. The heater is 3.8V 0.72A, u=17, S = 3.0mA/V Max. anode voltage is 400V.The valves are NOS, but the boxes are mostly in bad shape. Pictures are available by e-mail.
Please contact me if you are interested.

Regards,

Arnold Goksyr

DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://www.demostenes.no

Thousands of different valves in stock as well as sockets,transformers,books,caps,resistors and other components. Web site is updated every week. You can order on-line.

2402. Re: low freq PLL for jumpy FM carrier tracking?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-28 15:23:55 UTC
From: Jan Wagner <jwagner@cc.hut.fi>
Message-ID: <3CA3358B.EEF097E1@cc.hut.fi>

> and the CD4046/74HC4046/4096 chips.

Yeah I've tried those. By choosing resistors R1 and R2 on the VCO, it works fine, but only for a fixed range. Can't change the range in 1.0 kHz steps, digitally...

So the problem is, how to make it digitally tunable? i.e. shift the 30kHz lock&track range up and down according to the users wishes (not with a potentiometer! as it should be digital)...

I'd figure that a PLL low freq FM (or even AM!) radio receiver style setup should work for my project. Maybe someone here has already built a PLL MW receiver? And could suggest which PLL chip works well for this?

The other option was to just limit the PLL VCO input voltage to a specified, changeable range, but VCO freq vs input voltage linearity being what it is (+-1..+-10%), this will not give good tuning and also makes the system more sensitive to noise.

> (It does seem like what you really want is simply a power oscillator
> which uses the resonance of the coil to determine frequency...but I
> don't claim to know anything about Tesla coils.)

That certainly would be the simplest approach, and it would work very well were it not for that the Tesla coil (which is _really_ nothing else but a big single-layer solenoid coil) has multiple resonant frequencies quite close together, and even the unloaded and loaded system resonant frequencies differ by some 10kHz...

So a direct feedback thingy will allow locking to other than the fundamental. In the worst case the high voltage breaks out somewhere along the coil, and not from the dedicated full-metal breakout point on the top, and at the powerlevels involved (>500W) the coil will burn up.

Since the VCO center is set by a resistance to ground, just synthesize
that with a DAC controlled circuit. For example, if you drive a
multiplying DAC with the voltage on that PLL pin (through a simple
unity gain buffer) and connect the MDAC output (perhaps buffered to a
voltage output, if needed) through a resistor back to that pin, the
current in the resistor will be proportional to the voltage and to the
MDAC setting. You can add DC biases so that the tuning range is
limited if you wish. It appears the lock range setting is even
easier, since the voltage on the pin appears to be a constant; you
need only set the current taken from that pin.

Or...just do it all in a DSP.

...

Ah, then perhaps it would be good to design the coil so that it does
not have so many nearby resonances! Surely there's not much advantage
to them??

Cheers,
Tom

Hi all, anyone remember where the info was about converting old
microwave oven H/V transformers for use in H/V power supplies?? I
remember something about needing to remove a piece of metal on the
inside of the windings to be able to use them for H/V power supplies for
amps. if anyone remembers where I can get this info or which magazine it
was in I would appreciate this. Thanks in advance for the time. I
have been collecting many of these and would like to start building some
R-F amps for 75 and 40 meters for fun. 73' DE AA8WL

Sam:

It was in Electric Radio a couple of years ago.

What you will see upon inspection of the transformer is some extra laminations on both sides of the cental core, between the primary and HV windings. You can drive these out with a punch and hammer, although from personal experience it is easier said than done, and you have to be careful not to damage the windings in the process.

The best article I know of was in QEX some few years ago. Don't remember the date. Maybe you can find it or a reference to it on the ARRL site The shunts are very obvious in these xformers and can be removed by hammering them out. Some are tighter than others, so be careful not to damage the windings. Also, we are talking about 2000+ volts, so be CAREFUL. They can be lethal!

73, Phil, N4CWX

2413. Re: re:useing old microwave H/V transformers for P/S'

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-29 15:37:33 UTC
From: Roger Leone <arleone@inreach.com>
Message-ID: <9S%o8.1090$_41.103567415@news.inreach.com>
Source record: 45205

The magnetrons that these transformers are intended to power would draw excessive current without these shunts in the transformer. But in the kinds of applications most hams have in mind, it is not desirable to limit the current that can be drawn, so removing them is necessary to take full advantage of their ratings.

If you look at non-microwave oven transformers, you will not see such shunts.

Roger

Spring has sprung and the seasons first FLEA at MIT
is just a month away.....

*** GREAT NEWS We again have full use of the garage and outdoor
lots for sellers !!!

****
****

Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 21st 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available untill
April 21st which offers a 33% discount. See the
registration form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

Reminds me of why I like Digi-Key. This morning at 1:30 AM, I created an order on their site for about 30 different line items, mostly surface-mount parts. I wrote in a request for FedEx Saturday delivery in their "Order Notes" field, typed in my credit-card number, and hit "Submit." At 8:16 AM, the package's tracking # appeared in my mailbox.

No printing out my own order form, cleaning out the ATM and waiting in line to buy a money order, addressing an envelope, and waiting for the US Pony Express to truck my order to Montana and back, where the proprietor might or might not have been eaten by wolves last Tuesday. I mean, geez... most small-scale vendors don't have Digi-Key's level of business infrastructure, but the least they can do is answer their phones and take PayPal or other forms of net-compatible payment.

To Dan's credit, though, I've bought from him on eBay and always received great stuff at great prices. He has started new auctions (under the user ID 'twisttwinkel') within the past week, so I don't think the eaten-by-wolves scenario is likely. Probably just swamped with eBay business at the moment.

I have to say I'm a huge fan of DigiKey. While they are definitely not the low-priced spread, their prices aren't bad, and their customer service is nothing short of stellar.

But they don't have much in the way of RF parts. Dan's has a lot of stuff you can't get elsewhere, or that would be very expensive elsewhere. And while the whole snail mail thing makes getting the order pretty slow, he does provide nice stuff.

Having discovered radioshack.com (not your grandfather's Radio Shack) and kitsandparts.com, though, I have to admit to ordering from Dan's less and less. Diz (kitsandparts) has toroids at far better prices than anywhere, although you do need to order quite a few, and rs.com has pretty much everything, although their toroid prices are a tad high, and their shipping is high for larger orders (but interestingly they have the best shipping deal for small orders).

Still, though, Dan's transformer kit is hard to beat - if you don't make hundreds of mixers you would end up spending a ton of money for the same thing, and for some semiconductors, the only other choice seems to be RF Parts, whose prices are breathtaking. And for weird little bits of hardware, where else can you go?

..

2425. Can one substitute transformer wires and cores?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-30 14:50:01 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203300650.1ab54362@posting.google.com>
Source record: 45217

Although I am new to homebrewing, I already have a pet peeve: circuit projects that require parts that aren't available at Radio Shack or local electronics stores. I don't like the idea of spending $5 in shipping to buy $5 in parts or having to gather a list of all parts needed for all possible projects I want to build so that I only have to pay for shipping once.

I find that transformers are my biggest source of this pet peeve. One project I am working on requires an Amidon BLN-43-2402 ferrite binocular core. Other projects require different cores. One project requires #30 enameled wire. Another project might use #24 wire, and something else might use #28 wire. I am reading the transformer section in _The ARRL Handbook_, and I notice that some of the important parameters include the efficiency factor, core permeability, and coupling coefficient.

Can anyone tell me the process you go through when substituting transformers? It seems to me that if you know what frequency RF the transformer will be handling, the amount of power it will handle and perhaps other performance factors, then you can understand what you need. It also seems to me that these performance parameters are determined by design parameters like the size of the core, the shape of the core, the permeability of the core, the thickness of the wires, the number of turns used, and perhaps one or two more factors I am overlooking.

Can anyone shed some more light on just what performance requirements you have for a transformer and how you decide on the design parameters? I think the parts listed for projects in the ARRL books were chosen because the individual author of the project had an excess inventory of the parts or was able to find these parts at his/her particular Radio Shack at the time. But then, what was widely available locally at one place and time may not be available here and now.

Source record: 45218

Jason:

You have put your finger on what I have heard called "homebrewer's lament". It isn't easy to find parts that are affordable, easily obtainable, and identical to the ones in the designs you are following. You often have to go to several (or many) parts sources and deal with shipping charges, minimum orders, handling charges, back order delays, etc. When you add it all up, you find that it is more expensive to buy all the parts than it is to buy a commercially produced unit, which of course comes assembled, tested, guaranteed and has a repair facility with people who are familiar with its problems.

You can sometimes substitute parts you have on hand, for exemple instead of the specified Amidon BLN-43-2402 core you could use one you salvaged from an old TV 300/75 ohm balun. But the results you get can be disapointing. And when you have substituted many parts in order to use what you have on hand, and the device doesn't work, what part do you blame? For that reason, you should always try to follow the original design as closely as possible.

These difficulties have made parts kits popular. Many authors know how difficult it can be to find parts for their projects so they make kits available or at least let you know where you can get the parts. The DDS VFO in QST a few months ago is a good example of this.

Flea markets are also good places to shop for parts, but this favors a reversal of the parts acquisition process--instead of shopping for specified parts for a particular project, you see parts that are cheap and you find (or create) a project to use them.

If you have a room full of test equipment you can do measurements to make sure the parts you want to substitute are suitable. Most of us have very rudimentary test labs (VOM, grid dip meter, SWR meter) so we just use the "empirical method" (trial and error). Yes, the results are often disappointing, but the successes make it worth the effort.

No BFD...
Try 100pF to ground between the xtals and think 1500 ohms at
both ends. 4 xtals better. Try 100/150/100pF.
Use silver micas. Tweak from there.
If you want to vary the bandwidth, try 24/24pF in parallel with
matched varicaps run thru 100K resistors from 9-12V to a pot.
If 4 xtals, try 24/47/24pF plus the varicaps...

Hi,

On most projects you can go up (smaller diameter) two wire sizes without major problems. If the core will mechanically accept larger wire you can usually go down two wire sizes. With a #28 wire specified either #26 or #30 may work.

Magnet wire is generally the hardest thing to find. One unusual source is the inside of dead power transformers. It's a pain to take them apart, but the wire is free. Another local source is an electric motor repair (re-wind) shop. They use a wide range of wire and the 10 feet that will last you a lifetime is scrap to them. They use it a couple of hundred feet at a time on a large motor.

The best bet for cores is to buy the "experimenters kits" that most major core manufacturers sell. Generally you get 5 or 10 of each of a variety of cores. Amidon, Feronics, MicroMetals, and Fairrite all have pretty good kits listed on their web pages.

If you do order up normal cores the next problem you hit is a minimum order limit that is pretty steep. About the only way around this is to order a range of materials and diameters so once the order comes in you have a lifetime supply.

Hamfests and various junk sales are also a good source of some of this stuff. I have found spools of magnet wire gathering dust in some of the oddest places. Generally a couple of bucks will buy a spool of what ever they have. Unlabeled cores are the same kind of thing. If they don't know what they have they generally sell them dirt cheap. You then have to take them home and figure out what they are, but that's not to hard. Throw a few turns on them and measure the inductance. That will give you permeability and narrow down the material pretty quick.

Most of us have boxes and boxes of all sorts of weird parts that are waiting for a project. It's pretty much the only way to get around spending a bunch of money every time you want to do anything at all.

Don't know if any of that helps or not ...

Take Care!

That's actually been changing over the past couple years. They actually
have a pretty decent selection of RF parts if you don't count specialty
items like bare toroid cores and the like. Probably 75% of what Dan
sells, although their prices on RF parts really are stratospheric
compared to Dan's.

Seems like every other DigiKey catalog I get has at least one new
distributor line added to it. It was certainly nice when they started
carrying Atmel microcontrollers....

> local electronics stores. ...

As a couple other posters noted, you've identified a real problem. If you are willing and able to accumulate a "junquebox" of parts, before long, you'll find you have on hand _most_ of the parts needed for many projects. Of course, you're likely to accumulate the parts that are most interesting to the type of project you gravitate toward. By the way, though I said "junquebox," you'll serve yourself very well if you put some time into organizing your stockpile. If you're willing to do surface-mount work, you'll find that you can put a LOT of parts into a small volume. I'm using inexpensive coin envelopes for many of my SMT parts, and a very few index-card file boxes (or similar) end up holding well-sorted sets of resistors and capacitors and the like.

As another poster mentioned, one partial solution is having a way to test things and find out if they work like the original design intended, even though you've had to use different parts. It's certainly possible to build some very helpful test equipment, if you can't afford to buy it, but also as you learn more you may be able to get to a point where you can change designs, or make your own designs, and know they will work because you designed them to. I think it's an iterative process: you build, test, learn, try things on your own, learn from them, learn to glean more out of someone else's design than just copying it, etc.

If you can talk yourself into space for parts storage, you can surely get lots of cheap parts by taking apart boards. As you build some things, you'll note that some parts are used over and over...certain resistor values, capacitors for bypassing where the value isn't critical, etc., and you can think about buying those in hundreds (or maybe even more) and get them a LOT cheaper than if you try to buy them in singles.

And then there are some "old farts" like me who have way more parts than we'll ever use...if I could find a local 'sperimenter who wanted parts and had a plan that involved learning something along the way, I'd be more than happy to supply the parts, and consultation too if asked. But it seems like there aren't a lot of people really interested in trying to build things from scratch.

Cheers,
Tom

2432. help needed with Yaesu FT-101ee

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-30 23:27:18 UTC

I just burned out a final tube (6JS6C) in my Yaesu FT-101ee today. I wasn't sure of the cause and still am not, but when I placed the bandswitch in the 160 meter position, and with the heater activated, the radio lights went dim. By the time I switched bands, the one final tube was gone. This all happened without activating the PTT. I wanted to find out what happened, so I reinstalled the good and bad tube and duplicated the conditions: 160 meters, heater on, PTT not activated. Immediately, the lights dimmed once again and the IC soared to over 0.15 mA with the bad tube in place. None of the other bands cause this problem. With the tubes removed, the "short" doesn't occur on 160. What can be the problem? At first, I thought the tubes but why wouldn't the other bands cause the same results? I did recently rewire the transceiver to enable the CW position to be able to use the AM filter. Could a rewiring mistake cause the symptoms on 160? Note that I also get a strong CW sidetone when the bandswitch is in the 160 position and mode on CW. This is only when the tubes are in place. Heater on and PTT not activated.

Can anyone help me figure out what the heck is going on?

Thanks,
AB

Source record: 45234

A while back I posted a not to the effect that I would like
to build a 10 meter antenna tuner.

Thanks to all the people who replied. One fellow in England was
particularly helpful.

I sort of solved it myself. I have a tiny MFJ tuner, and it works fine
on ten. So it is indeed the size of the beast. Bigger ones have
longer wires, more stray junk, and so they don't like ten meters.

I've even figured out how to design one. I just don't know the range
of resistive and reactive components that a t-network should cover.
I think my old Millen tuner does tell you what it will handle..

Thanks again to all

Mine did the same thing...the tubes went into self oscillation when
power was applied and they were executed in the proccess (well one was
anyway). Nothing was wrong with the radio...check the output PI
network for any damage caused and replace the finals..if you use
Sylvanias replace the 100pf cap in sreies with the neutralization
variable with a 10pf silver mica piece.

Thanks Art. I also noticed that, while unkeyed on 160 meter position, I get CW sidetone through the speaker, when switched to CW mode, with the good and bad tube still in place. The sidetone doesn't start until the tubes start warming up. Of course, none of these symptoms are present when I remove the tubes.

A strange, very isolated phenomenon to say the least! At first, I thought I rewired the switch incorrectly after installing the AM filter, but then the symptoms wouldn't occur once the tubes were removed.

I just received this radio by mail a few weeks ago and the tubes weren't removed during shipment. I wonder if this could have weakened them. Before I even modified the switch, I had to replace several components in the bias network because the current had soared.

Just looked over the manual, stared at it for a while, and not knowing exactly what you did to enable cw thru am filter, can suggest to check for obvious wiring mistakes. But further, with PA tubes pulled, can you get a wattmeter hooked to the "RF OUT" jack? This is the low level driver output for a transverter, etc. Should be on the rear next to the ground terminal. I suspect that for some reason you get the sidetone osc enabled with no key connection(which I recall trips the vox and keys the rig), and this is just blasting full drive to an untuned PA. Remember, the tuning is VERY broad on 160. You'll get drive no matter where the drive tuning is set, in my experience. It may not have done this on other bands simply because the setting of the driver tuning was not peaked for that spot on the band.

However, the only in 160 thing about sidetone really suggests a wiring mistake, that you'll need to trace.

Hope you find it. These are fine radios, I have three...

Hi,

I'm thinking of building a antenna analyser- the commercial ones seem pricey for what they are and the principles don't seem that complicated. Anyone already tried this for VHF (and UHF)? I've seen the website for a LF verison but my interest is more 50MHz > 146MHz and (idealy) 430>440MHz.

73

2442. Q of two coils in series

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-31 11:25:28 UTC
From: la8ak.xnd@online.no
Message-ID: <3ca65859.30988286@news.online.no>
Source record: 45232

Hi

What is the formula for calculating Q of two coils in series? In this case I wish to connect a 1.8mH coil (Q=650) in series with a 150�H coil (Q=50)
I am quite aware of calculating series resistance and adding for the two coils, ending up with Q=435 on 150kHz, but hoped it was an easier way for the next calculation

A side note -- did u check the power at the input to the tuner --- then
the output??
Those tiny tuners can soak up power.
Some get downright hot and arc over with too much input power.

Jan-Martin,

Problems like these can be solved using a spreadsheet, but I prefer Mercury since the formulas are entered in the form that is the most convenient, and Mercury solves for the unknowns. You can also add comments to each line in Mercury to show the purpose. This makes it easy to understand the calculations later instead of having to figure out what each cell refers to in a spreadsheet.

After entering the equations, you can save them to a file to provide a permanent record of the calculation. You can easily update it for different values.

Here is the result using your data, assuming no mutual coupling between the inductors:

```
Problem: C:\EU\XL.002
; inductive reactance, Q of coils in series

pi = ï¿½ ; enter 3.141...
L1 = 1.8e-3 ; first inductor value
Q1 = 650 ; first inductor Q
L2 = 150e-6 ; second inductor value
Q2 = 150 ; second inductor Q
F = 150e3 ; operating frequency

XL1 = 2 * pi * F * L1 ; calculate reactance of L1
XL2 = 2 * pi * F * L2 ; calculate reactance of L2
XT = XL1 + XL2 ; get total reactance
```

```
R1 = XL1 / Q1 ; calculate resistance of L1
R2 = XL2 / Q2 ; calculate resistance of L2

RT = R1 + R2 ; get total resistance in series
QT = XT / RT ; calculate total Q

Solution
L1 = +0.001800000000000000
Q1 = +650.00000000000000
L2 = +0.000150000000000000000
Q2 = +150.00000000000000
F = +150000.00000000000
XL1 = +1696.46003293849
XL2 = +141.371669411541
XT = +1837.83170235003
R1 = +2.60993851221306
R2 = +0.942477796076938
RT = +3.55241630829000
QT = +517.34693877551

This shows the Q is slightly higher than your value of 450.

Mercury is an update of Borland's Eureka 1.0 for the IBM PC, and
runs in DOS. You can get it at

http://archives.math.utk.edu/software/msdos/calculus/mrcry209/.html

(Yes, the url is correct:)

Best Regards, Mike
```

2446. Re: Q of two coils in series Oops!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-03-31 15:35:38 UTC
From: Mike Monett <mrmonett@yahoo.com>
Message-ID: <3CA72CCA.EA6@yahoo.com>
Source record: 45237

Mike Monett wrote:

[...]

Mercury also makes it easy to find mistakes, such as my typo when
entering the Q of the second inductor. Here is the revised calculation:

```
L1 = 1.8e-3 ; first inductor value
Q1 = 650 ; first inductor Q
L2 = 150e-6 ; second inductor value
Q2 = 50 ; second inductor Q <--- typo corrected
F = 150e3 ; operating frequency

Solution
L1 = +0.001800000000000000
Q1 = +650.00000000000000
L2 = +0.0001500000000000000
Q2 = +50.000000000000000
F = +150000.00000000000
XL1 = +1696.46003293849
XL2 = +141.371669411541
XT = +1837.83170235003
R1 = +2.60993851221306
R2 = +2.8274333882308
RT = +5.4373719004439
QT = +338.000000000000
```

Now the Q is lower than your value!

That little 150uH really kills the performance.

Best Regards, Mike

Hi!
I'm planing to home made a
RF power amplifier.But in
our country I can not get Amidon's products(FT series), I can
get the torid core, some of them ,can work in 0.5-30MHz,
but"Mi"is too low,only have50-100,not as FT series of Amidon.
my question is:
How can I
I use them in HF power amplifier as transformer and
LBF inductor replace FT and T series?
I think I can not use the brass tubes in the transformer
of HF power amplifier because of it
has verylow Mi.
Thanks in advance
73! Xu

Check the links at http://www.qrparci.org - there are dozens of them.

Also, take a look at the Fireball 40 on the NJQRP site - I think they still have the manual there. They sold it as a kit, maybe still do, but it's pretty simple.

For a transmitter only, it's pretty simple as long as you don't need a lot of frequency agility. A crystal oscillator or VXO, followed by a simple amp and some filtering is all it takes. If you want significant frequency agility, tho, the VFO itself can be a bit of a challenge. Take a look at NorCal's SMK-1. They don't sell the kit anymore but the schematic is typical of a pretty minimalist rig - they use a VXO with not a lot of movement. For another ratchet up in complexity, look at K8IQY's 2N2/40 - both are transceivers, but you can certainly rip off the transmitter circuitry. I don't know if it's anywhere online, but the G-QRP circuit handbook shows a "G3XMI Crystal Bender" which gives quite a lot of range on 40 from a VXO. Also, there's a ton of stuff in W1FB's QRP Notebook from the League.

George,

Thanks for the tips. I'm relatively new to the Yaesu series, so any advice is helpful here.

After I installed the AM filter in place of the CW filter, I rewired the switch according to some instructions I received, which I believe are from the Fox-Tango group. However, I received 2 sets of instructions and both are different, unfortunately. The first time I rewired the switch, I had CW sidetone on all bands and both in receive and transmit. Going by the other instruction sheet, I eliminated the sidetone and everything seemed normal until I went to the 160 position and that's when my problems started. BTW, I will post a drawing of the switch rewiring arrangement if you wish.

I removed the 2 final tubes. I still get normal RF drive and modulation on all bands. However, everything on 160 is ok until I switch to CW. I then get sidetone on receive as soon as I switch the heater on. With the heater off, I don't get sidetone. I get transmit modulation on all mode settings, including CW! No sidetone present during modulation. Time to recheck the switch rewiring!

The principle is the same, so if you rip off the circuit from an HF analyzer you just need to futz with the directional coupler to make it reasonably good at VHF. I doubt sensitivity will be an issue, you just need to work out the mechanics so the thing doesn't look like a short at VHF/UHF. You may also want some faster diodes but this shouldn't be a big deal.

If you already have an SWR bridge, I'd work out the coupler first. Just build yourself 2 dummy loads, a 50 ohm and a 100 ohm with enough power for your transmitter (at it's lowest power probably). I would simply fool with the geometry until I got the SWR of the coupler down to something tolerable. I doubt you will have any trouble with sensitivity - it seems pretty easy to get a few volts of RF out of one of those things. You need the 100 ohm dummy load to satisfy yourself you can sense the reverse voltage as well as the forward. Also, you will use it to calibrate your analyzer - it should show a 2:1 resistive SWR.

If you don't have an RF voltmeter you can build an RF probe easy enough to prove it works before you go building up the analyzer circuitry.

Also, be careful about the resistors. QQ this quarter had an article showing "noninductive" resistors with like a 10:1 SWR at 6 meters, even though they were reasonably flat at 80.

I picked up an old homebrew receiver a couple days ago at a yard sale. The old man said he made it from a kit, but doesn't remember who made the kit. It is a 2-tube regen (6SN7, 6AW8A), and uses plug-in coils. There are only two knobs: tuning and regen, no volume. Does this radio sound familiar to anyone? Any clue as to what the kit might have been?

The Arkansas QRP Club sells the original Tuna Tin 2 kit for $12.00....grab
that and you're on 40m in about an hour.

Here is a great place to look at one:

http://clocksusa.com/tuna/tt2page1.html

The Tuna Tin 2 is now available in kit form from the Ft. Smith QRP Group.
Your cost just $12 U.S. each which includes shipping/handling.
Group buys of 10 or more $10 each and shipping is on them. Foreign $15 U.S.
Make checks payable to jay Bromley

2457. Re: Home Brew Antenna Analyser

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-01 01:48:04 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <a88etd$8jq$1@slb6.atl.mindspring.net>
Source record: 45248

There are a couple of choices for methodology... Either use a single frequency source which you can set to the desired frequency, or a wideband noise generator.

If you have a signal generator, I'd suggest a CAREFULLY consructed toroid bridge and I would use AD8307 log amp chips for the detectors.

Diode detectors get non-linear and show "odd" responses depending on drive level. Kinda hard to get a number that can be trusted.

AD8307 chips repond up to 600 MHz and are truely logarithmic.

Check the kanga website:

http://www.bright.net/~kanga/kanga/

They have the kit of parts for the logamp power detector.

==========

If you build a wideband noise generator, you could either use a receiver or, better yet, a spectrum analyzer to look at the return signal.

A spectrum analyzer can show where the match is in terms of frequency, and how good the match is as well.

So, a wideband noise generator, a toroid bridge, and a spectrum analyzer can tell you a lot about how the antenna is performing.

Hi.

If you follow-up to one of these newsgroups, could you please CC.
your reply to my E-mail address, if possible?

I recently purcased a used TS-940. Although the manual was included,
it was not very forthcoming about the details of the two "Accessory
terminals". "ACC1" is a 6-pin DIN connector and the manual has no
information whatsoever about this connector. "ACC2" is a 13-pin
DIN connector and, although the manual at least labels these pins,
it has no information on how to use its connections.

I am wondering if anyone can point me to any internet-accessible
interface protocol specification for these two connectors. I would
like to obtain enough information to home-brew a hardware interface
to the shack PC, and to write my own software for things like
controlling the TS-940 from the PC, automatic log entry of time,
frequency, etc., if this information is availablve through the
interface. In addition to any available protocol specification,
any articles, application notes, etc. would also be useful.

Thanks and regards.

Another very good posibility since you mentioned the bias reworking is
that the radio was at one time used on CB and is "cooked"...a lot of
these radios saw cb service at the 100 watt level and payed the price
for it. Check out an EXCELLENT ft-101 site at:

www.qsl.net/nw2m/ft101.html

Best site on the web of info.

Hmm... not a bad idea at all! Actually very good! Many thanks for the
tip!!! :o)

> Ah, then perhaps it would be good to design the coil so that it does
> not have so many nearby resonances! Surely there's not much advantage
> to them??

Yup, no advantage, but there isn't much that can be done about this...
Because of the high voltage, the coil must be air-cored and
single-layer. Ferrite cored and small would be nice of course, but it
is not practical here. The only thing is an optimum height-diameter
ratio. Well, anyway, see for example
http://ourworld.compuserve.com/homepages/alansharp/
http://ourworld.compuserve.com/homepages/alansharp/UK2001.htm
then you will know why... ;o)

cheers,

2469. Antenna for 2m

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-01 16:34:47 UTC
From: Martin Wehner <martin@cyclotomic.com>
Message-ID: <3CA88C27.AC8A73D5@cyclotomic.com>
Source record: 45260

Hello All-

I am interested in building an antenna for a 2m handheld and have a few questions. Any input would be greatly appreciated.

The handheld I currently have is a Icom IC-T7H, 5W max output power. I am currently using the supplied Icom FA-1443B dual-band antenna (VHF/UHF).
I am interested in FM on 2m only and don't care if the antenna I build cannot do UHF.

Here are my questions:

(1) Do you even think it's worth doing it? Can a low-power radio such as mine even power a home-built antenna? Has anybody here used this transceiver with a home-built antenna before?

(2) I am very worried about damaging the radio. Are there any checks I can perform before hooking up my home-built antenna to the transceiver?

(3) Currently I am planning on building an antenna I found in the ARRL Handbook: the "1/4 lambda antennas for home, car and portable use" project (basically a vertical with ground-radials mounted at its base). Has anybody ever built that one? How well did it work?

(4) Do I need a balun for the antenna if fed with coax? If I do, how would I go about building/buying one? Is a balun just a transformer that matches the imepedance of the feed-line to the antenna impedance (e.g. if you use 75 Ohm feed-line, but use a 50 Ohm antenna, would you use a transformer with coil-resistances of 75 Ohm and 50 Ohm, and a turn-ratio of 1:1)?

(5) I also read the chapter about transmission lines and understand there is a problem with using long runs of coax for VHF frequencies. How long can I make my transmission line before a noticeable degradation occurs?

(6) What would I use for my transmission line? All I currently have at home is RG59/U coax from television installations. Does coax like that work? Should I definitely get a different kind? If so, where can I buy different coax (I live in San Diego, CA. I do know of two fun electronics places: Gateway Electronics and Murphy's in El Cajon)?

(7) What is the best place to buy the hardware from that I'll need for construction? The project in the Handbook calls for brass or steel rods. Does the Home Depot carry that kind of hardware? If not, I also know of an Ace Hardware store around here: would they carry it?

(8) I am planning on sticking the antenna out in my back-yard somewhere. Does anything speak against using a simple PVC pipe to raise the antenna off the ground?

(9) Does the antenna need to be connected to a ground rod? I guess I don't quite understand why some antennas do have to be and some don't. It seems that HF antennas need to be connected to a good ground system, whereas these don't.

Thank you for reading this far. I realize these are very basic questions, but we all have to start somewhere. Thank you for any and all input you may have.

No, but a tape measure, wire and insulators were in vogue back then, as was common sense. I'm not sure as to why vector network analyzers, Boonton RX bridges and time domain reflectometers missed being named as additional tools needed to understand and use a radiator.

I do believe however that 3 or 4 of those entities came after OH2AQ and they played a part. (The rest were countries before that became so obviously dumb.)

I've not tried that radio with a homemade antenna but there's no reason it
shouldn't work.

>(2) I am very worried about damaging the radio. Are there any checks I
>can perform before hooking up my home-built antenna to the transceiver?

I wouldn't be enormously worried about it. Radios have SWR protection
circuitry, it will cut power back if it detects something very wrong with
the antenna.

I presume that radio has out-of-band receive? I would check the NWS weather
radio frequencies between 162.4 and 162.55MHz. The local station in San
Diego should show a full-scale signal strength reading. (they're running a
LOT of power from a very good location!) I would expect to receive at least
one other station in that range though not being familiar with the San Diego
area, can't guarantee that.

If you hear the weather radio OK, I think you can be reasonably confident
the antenna is working well enough to not damage the radio.

>(4) Do I need a balun for the antenna if fed with coax? If I do, how
>would I go about building/buying one? Is a balun just a transformer that

>if you use 75 Ohm feed-line, but use a 50 Ohm antenna, would you use a
>transformer with coil-resistances of 75 Ohm and 50 Ohm, and a turn-ratio
>of 1:1)?

I've not used baluns with VHF antennas - I don't think it's necessary.

When you talk about 75 ohm feedline and 50 ohm antennas, you aren't talking
about resistance. If you take an ohmmeter to your antenna, you will read
infinity. (with some models of antenna, you'll read zero) 50/75 ohms are
impedances - valid only at the desired operating frequency. (your antenna
that's 50 ohms at 144MHz might be 3 ohms at 28MHz)

If you were to use 75-ohm feedline with a 50-ohm antenna, you would use a
1.5:1 balun at each end. (each end, because the radio is 50 ohms too)
Except again, I don't think it's necessary.

>(5) I also read the chapter about transmission lines and understand
>there is a problem with using long runs of coax for VHF frequencies. How
>long can I make my transmission line before a noticeable degradation
>occurs?

Depends on what grade of transmission line. RG-174 might only be good for a dozen feet or two. I use RG-213 on my 2m antenna, the feedline is about 50 feet long. Something better like 9913 would probably be a good idea but for what I do with it, my installation works well enough.

>(6) What would I use for my transmission line? All I currently have at
>home is RG59/U coax from television installations. Does coax like that
>work? Should I definitely get a different kind? If so, where can I buy
>different coax (I live in San Diego, CA. I do know of two fun
>electronics places: Gateway Electronics and Murphy's in El Cajon)?

RG-59 will certainly work. Except that you'll probably have a hard time getting the appropriate connectors on it. It is, as you mention, designed for TV work; most available connectors are of type F. You could use adaptors though those usually induce losses, sometimes severe losses. RG-59 is also 75-ohm impedance, so it will result in a slightly higher SWR. That said, 1.5:1 is not a big deal, I wouldn't let that inhibit me from using the 59.

I would be tempted to get something designed for ham work. RG-213 or 9913. There's a Ham Radio Outlet in San Diego that would carry that. (the other stores you mention might too, I'm not familiar with them)

>(8) I am planning on sticking the antenna out in my back-yard somewhere.
>Does anything speak against using a simple PVC pipe to raise the antenna
>off the ground?

As long as it's mechanically stable so that it won't come down, it should be fine. If you're putting up a ground-plane design like you describe, be sure the radials (the rods that stick out horizontally) are high enough that nobody will walk into them. You're probably going to have to use guy wires or ropes, I don't think a PVC pipe 8' long is going to stand vertically on its own.

>(9) Does the antenna need to be connected to a ground rod? I guess I
>don't quite understand why some antennas do have to be and some don't.
>It seems that HF antennas need to be connected to a good ground system,
>whereas these don't.

Some HF antenna designs use the earth as part of the antenna. A good ground system is important to performance; without it, it's like connecting a resistor in series with the antenna.

Most VHF antenna designs don't work that way; the entire antenna is self-contained. However, lightning and static buildup can still be an issue. I would still put a ground rod at the base of the PVC and connect it with a reasonably stiff wire (something like the #14 stuff used to wire electrical outlets) to the ground radials on the antenna. You don't need to bury radials like you would for an HF antenna though.

Cross-posted to: alt.ham-radio.mods,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

As most who read my posts are already aware, I have blown 6JS6C tubes in my FT-101ee. For replacement, I was going to try to obtain a matched replacement set until I found out the price. A well known firm just quoted GE and NEC prices for a matched pair of 6JS6C at $135 and $160, respectively. I recently purchased this FT-101 for $150, so it doesn't make much sense to spend more than I paid on a new set of tubes. So, I'm wondering about personal experiences converting to 6146B tubes, based on a fairly recent past QST article. Any successes, failures, or any other tips would be much appreciated.

Thanks,
AB

Hi all,

Thanks for taking the trouble to read this post.

I have a requirement to run a Desk top type PC base unit in my car, and wonder if anybody out there has tackled the problems of supplying the various voltages and currents from a 12 volt battery.

There are several companies able to supply Inverters that will do the job, but I have seen somewhere on the WWW where the motherboard was supplied from the cigar lighter socket. Can anybody point me to a solution please.

Thanks,

Chris G6KBC

I don't have a suggestion, but I have a comment. I remember when you could
get horizontal sweep tubes like 6LQ6, 6KD6, etc for about five bucks apiece,
and it wasn't all that long ago. Though the quality may not be equivalent
to domestic tubes, there are new [mostly audio] tubes coming out of China
and Russia for reasonable prices, and it really irritates the living heck
out of me to see these money-lusting opportunists driving the prices up on
American NOS just because there are idiots who will pay it while the rest of
us have to suffer without..

I don't know that you're gonna find 6146's any cheaper, cuz just about
twenty years ago you could rob them out an old commercial mobile rig or get
them from almost any local ham who had them laying around in the ham shack,
but from what I understand these are now difficult to find as well. Guys
used to give their old equipment away to people who needed it, but all of
sudden anything which is labeled as "vintage" or "obsolete" is made out of
gold, and people literally *hoard* it for the "collectibility" and make it
unaffordable to those of us who need it for practical or recreational use..

Fortunately, I have a selection of NOS audio and RF tubes to use as
replacements for my own equipment, cuz even though I can afford new tubes
i'd probably let my equipment sit on the shelf and gather dust before
catering to the "collectors" and greedy consumer slavemasters..

"The only thing is an optimum height-diameter ratio"?? I can think of quite a few other things you could vary. The obvious one that comes to mind is whether the winding is close-spaced or not, but there are surely others as well. There are some analogs with transmission lines and impedance transformations that are worth thinking about, I think. Perhaps the Tesla coil folk have thought all these things through a hundred times over, but it's always worth asking the question.

I'm glad to see from that reference that people are still using shock excitation. It can be quite efficient, actually. I understand that one of Marconi's later spark transmitters operated at somewhere around 1/3 of a megawatt output.

Cheers,
Tom

There isn't a simple solution. Most desktops require 5v at several amps as well
as +12v and -12v. Unless you want to cannibalize your PC an inverter is
actually a cheap/workable solution.

Okay.... Thanks for the comment....it was the "5v at several amps" bit that
concerned me the most, but there are some very resourceful people around,
who may have come up with an idea that had not occurred to me.

Chris.

> wondering about personal experiences converting to 6146B tubes

I had the pleasure of dealing with one of them attempts with an old cheap
guy next door who tried to do it to save $16 on tubes on the 70's.
Converting is a nightmare, if you dont know how to do it stay away.
First you have the a serious re-socketing/mounting issue/rewiring.
Then after that you find the ALC, neutralization, bias must be reworked.
In the end you will likely with end up with an RFI spewing oscillator ...its
not worth it
$150 is cheap for a 101EE pay the $135 or find some good pulls

Hi Jan-Martin,

Simply reducing Mike's calculations to a formula, you get

Qt = (L1+L2)/(L1/Q1+L2/Q2)

and in fact, it's just what you describe as well. You'll be helped
some if the coils share fields in a way that increases the inductance.

Cheers,
Tom

It is. In fact it is commonly done this way.
It is only necessary to unbalance the Mixer by a controlled amount.

Hello Doug-

Thank you for the prompt reply. And thank you for all the great advice.
I will certainly put it to good use!
I do have a few more questions regarding your response below. If you
have time, I'd greatly appreciate your input.

Doug Smith wrote:
> When you talk about 75 ohm feedline and 50 ohm antennas, you aren't talking

> *impedances* - valid only at the desired operating frequency. (your antenna
> that's 50 ohms at 144MHz might be 3 ohms at 28MHz)

So, theoretically, the impedances would have to be adjusted on the same
band as well, as the impendance will change from 144.0MHz to 148.0MHz,
correct? I understand that the changes will be quite small.

What does the impedance of a feedline depend on and how does it come
about?
Does the material the feedline is made of have anything to do with it?
Or is it mostly because the coax ultimately is like a network of
capacitors and inductors (i.e. it'll depend on the spacing of the
conductors and the dielectric separating them)?

> If you were to use 75-ohm feedline with a 50-ohm antenna, you would use a
> 1.5:1 balun at each end. (each end, because the radio is 50 ohms too)
> Except again, I don't think it's necessary.

Going back to this concept real quick:
I am under the assumption that a balun can be as simple as a
transformer.
How would I go about determining which transformer is appropriate for my
application?
I will go with your advice and get 50 Ohm feedline, but let's say I was
forced to use 75 Ohm feedline.
In that case, to determine which transformer is appropriate, would I
look at the transformer as a series network of a resistor and an
inductor (the resistance of the wire and the inductance of the coil)?
The wire-resistance will probably be negligible in this case, but I
wanted to check.
Would I then also have to choose it according to my operating frequency?
That would mean that, for a different band, I would have to put in a
different balun?
Also, what would I have to watch out for in terms of voltage and current
ratings? Does current flow on the antenna side of the transformer?

Also, suppliers like DigiKey make the distinction between
power-transformers and audio-transformers. What should I be looking for?

Thank you for any and all input.
I greatly appreciate your help!

Q is a property of reactance which may be either high or low, good or bad.

Like SWR, it is a quantity which is of little direct use except for calculating other characteristics of a circuit which ARE useful.

Q meters at least indicate what they are purported to measure. Whereas SWR meters don't, they delude the users.

2488. Time to think about running mobile?

If you are ready for a high performance multi-band HF mobile antenna, then I ask that you
visit www.qsl.net/k4kwh. This is a very heavy duty screwdriver-type antenna and goes beyond the cheap materials often seen in some others. Here are the basic specs.

Carolina Cyclone I

Full 2" loading coil (compare to 1 1/2" on DK3 copies)
#14 silver plated copper windings (compare to skinny little #16 wire on DK3 derivatives)
Wound at 8 turns per inch (compare to 10 TPI on DK 3)
Extra heavy duty finger stock using 1/4" wide fingers and extra springy for complete contact
(compare to the little copper or brass stuff that breaks easily)

Handles up to 800 watts SSB (Try that with a PVC screwdriver coil!)
impedance matching done with a simple little inductor at the feedpoint. No toroids to
give "finicky" performance/matching up on the higher bands.

And all without breaking the bank like those $300+ versions! Just $240 shipped to the
lower 48 states!

Hey, guys, it's SPRING (at least in the South), and it's time to get out and get that mobile
up and running!

2489. AM Transmitter project

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-02 00:21:44 UTC
From: Martin Wehner <martin@cyclotomic.com>
Message-ID: <3CA8F998.36D619D5@cyclotomic.com>
Source record: 45280

Hello All-

My question this time is concerning a simple AM transmitter project I've
been working on.
Since I don't want to have to build my own receiver (yet), I decided to
use a carrier-frequency of just around 1MHz, so that I can pick up the
signal with a conventional radio.
Let me state right away that I am only doing this for testing purposes.
My goal is not to play a prank or mess with another commercial AM
station's signal, I am just trying to learn.

What I have done so far is the following:
With some help from sci.electronics.basics, I believe I finally got rid
of the notion that in AM, the carrier's amplitude is changed over time.

I abandoned my initial designs and am now using a very simple design
that uses 4 diodes. The ARRL Handbook calls this arrangement "diode
double-balanced mixer".
However, I am not using the transformers that the Handbook uses, but
attached my carrier signal and modulating signal directly to the diodes.
Question #1: why are the transformers necessary? (I am referring to the
2001 ARRL Handbook, page 15.15)

I simulated the whole thing in Spice (without transformers); the output
wave-form did not look like what I expected for it to, but running a FFT
of the output in Mathematica shows that the carrier component is indeed
suppressed, and that I have a LSB and a USB.

I built the circuit and looked at its output with the oscilloscope. The
output wave-form did not look like what Spice predicted it would look
like, but I can live with that (after all my signal sources (RF and AF)
are probably less than perfect).

Question #2: what should the signal look like? Spice shows the output as
a wave-form that follows the modulating signal in shape, but made up of
the carrier frequency. It does not look like what I've seen as an AM
wave-form before, where you have the top and bottom of the output
"mirrored."
Sorry I am doing such a bad job at describing this. If necessary, I can
post the output to my web-site.

The oscilloscope shows the output as just a band, with no discernible
shape. It does look like I can see the wave-form jump up and down a bit
when the AF changes, but when I applied a sine-wave of AF frequency to
it, I didn't see the nice crisp shape I expected to see. When I trigger
on the output signal itself, I can see the carrier frequency in there.

Question #3: Does what I see on the scope indicate that I am not modulating the carrier enough?
How would I go about changing the amount of modulation? Would I have to change the amplitude of the input signals? (Only possible to a certain extent, unless I build separate amplifiers).

Note: I built the circuit on solderless breadboard by simply inserting components (without cutting their leads) and connecting nodes with wires where necessary. I am using simple 1N914 diodes. The carrier and AF source's amplitudes are the same as the ones I used for the Spice simulation.

I used a standard radio and was able to pick up the signal I was producing.
The interesting thing about this is that I was able to pick up the signal without any antenna attached to my circuit.
The signal I picked up was very weak and changed strength, as I moved the receiving radio around my circuit.

I then built a simple amplifier circuit, using a standard NPN BJT as amplifier (a simple Class A amplifier, if I am not mistaken).
I am having a hard time looking at the signal on my scope, but it does look like the amplitude is greater now.
In any event: signal reception was not improved even with the amplifier in place (I built it for 10x amplification).

Question #4: What kind of an antenna could I hook up to my circuit? At a frequency of 1MHz, the signal's wave-length doesn't seem practical for the methods outlined in the Handbook.
I tried connecting just a piece of wire to it and connecting another wire of equal length to my power-supply's ground in a feeble attempt at making a dipole, but to no avail. If something like this should work, what kind of wire should I be using?

Question #5: I am a bit confused as to what the power-ratings for radios mean.
If I say I am transmitting at 5W power, what does that really mean? Does the standard: P=V*V/R still hold? In the standard case of dealing with a 50 Ohm antenna, does that mean my final amplifier is outputting a voltage of +/- 15.81V across the antenna terminals?
Does that mean that you may have hundreds of volts across the terminals for higher-power transmitters? How do you obtain these voltages? Would you use a transformer and then connect the antenna terminals directly to the transformer? Or does your actual power-supply have to supply these voltages?

Thank you for reading all this. Even though my questions are very basic, I hope somebody out there can give me a hand in figuring out these things. Any help will be greatly appreciated!

Thanks in advance! 73's

Martin

The impedance change may or may not be quite small over the band, depending on the antenna. However, the 2 meter band is fairly narrow, compared to it's frequency, so it's not a big problem. Back when repeaters were always aboove 146, we always used an antenna for 147 for FM and one for 145 for SSB/CW. Since they were polarized differently it made sense to have 2 antennas anyway, but they were different sizes because of the different frequency.

> What does the impedance of a feedline depend on and how does it come
> about?

The impedance of the feedline depends on the geometry of the line and the materials.

> Does the material the feedline is made of have anything to do with it?
> Or is it mostly because the coax ultimately is like a network of

> conductors and the dielectric separating them)?

You got it. But there are some differences in dielectric coefficient between different insulators.

> different balun?

There are balun designs that work at a single frequency, and others that are very broadband. It depends on the particular design you choose.

However, in the case of 75 ohm vs. 50 ohm, I would be careful of my choices, or perhaps just ignore the difference. There will be some loss going into the 75 ohm feedline, but there are likely to be larger losses by inserting a transformer. Balun is probably inappropriate since both the input and output are unbalanced.

Probably more significant is the line loss. RG-58 has a loss of about 6 db per hundred feet at 2 meters. Good quality RG-59 should be similar, but good quality RG-59 is pretty hard to come by. The sort of RG-59 you find for TV installations is probably twice as lossy or worse.

Obviously, whether this matters depends on how long your run is. A quarter wave isn't all that great an antenna, but the little antenna that came on your HT is probably 6-12 dB poorer, so if you have a 50 foot run, you're still better off, plus getting the antenna higher is what matters at VHF. It's almost all that matters. Sure a little gain is nice, but no matter how much gain you get, getting the antlers up another 20 feet will make a bigger difference.

If you have a longer run than 50 feet or so, I would go to a larger cable. RG-8X has about 4 dB per 100' and 9913 about 1.6. There are several other flavors inbetween, with cost pretty much related to loss. 3 dB is barely perceptible, so if you have a 50 foot run, getting something better than RG-8X probably will be wasting money. If you have a 200 foot run, though, you better get some nice coax.

> Also, what would I have to watch out for in terms of voltage and current
> ratings? Does current flow on the antenna side of the transformer?
> Also, suppliers like DigiKey make the distinction between
> power-transformers and audio-transformers. What should I be looking for?

RF transformers aren't like audio transformers. You do need to worry about voltages, and the voltages can be astonishingly high. You can use Ohm's law to calculate the voltage into 50 ohms based on your power - *BUT* that assumes a perfect antenna. Anything less than perfect multiplies the voltage, potentially by a lot. If you intend to use one antenna on multiple bands, common on HF, not so common on VHF, voltages 10X what you would calculate based on your power are not unusual. If you are making a resonant antenna for a single band and are reasonably careful in your measurements, 2X ought to be a reasonable margin.

You can't go to DigiKey and buy the things, tho. For some cases you can buy something off the shelf, but it's more common to build something, often using several different types of coax to make the transition. At HF, hams sometimes use 450 or 600 ohm feedline. In those cases where the impedance transformation is very large, they may very well wind a transformer that looks sort of like an audio transformer, but with a different core material. For smaller transformations, though, 2 different types of coax are generally used. There are probably dozens of designs in the handbook.

Actually, my own antennas have usually been tape measure and insulators... I am fond of 40 meter dipoles since they load on 15 well enough.

Of course, I also tend to use a radio with a tolerant pi output matching system and they'll load up into darn near anything.

Heck, my last antenna was a wire down the hall and hooked to the refridgerator door. I tuned it by opening the door until I got a decent match.

Fancy test gear has it's uses, but for most ham applications it may be overkill. Nice to use if somebody has one, but not really necessary in my opinion.

Most dipoles or yagi's when built to the right dimensions work nicely.

Now, if you want to fool with fractal antennas, an antenna analyzer will be a big help....

Yes, and yes. The impedance will vary across the 2m band, but the variation
will small enough that you can ignore it.

>What does the impedance of a feedline depend on and how does it come
>about?
>Does the material the feedline is made of have anything to do with it?
>Or is it mostly because the coax ultimately is like a network of

Mostly, the ratio of the diameters of the inner and outer conductors.

>Going back to this concept real quick:
>I am under the assumption that a balun can be as simple as a
>transformer.
>How would I go about determining which transformer is appropriate for my
>application?

Yes. Actually, "balun" is often a misnomer. (including in your case) It's
actually a "broadband transformer". "balun" is really only correct when one
side is balanced and the other isn't. But everybody knows what you mean<g>.

There are two other ways to handle impedance transformation in your case.
One would be to use a length of transmission line of impedance *between* 50
and 75 ohms. (I don't recall the formula) The other would be a literal
tuned transformer, with primary and secondary inductances. That scheme
would be tuned to a specific frequency and depending on "Q" might not work
across the whole 2m band.

The typical windings on a ferrite core is simply more practical, smaller &
easier to find the parts. Except that I don't recall whether most of them
are actually effective at 144MHz?

>I will go with your advice and get 50 Ohm feedline, but let's say I was
>forced to use 75 Ohm feedline.
>In that case, to determine which transformer is appropriate, would I
>look at the transformer as a series network of a resistor and an

>The wire-resistance will probably be negligible in this case, but I
>wanted to check.

Ignore both the wire resistance and the coil inductance. The radio will see the impedance of the antenna, modified by the appropriate transformation ratio. In your case, you would need a 1.5:1 impedance ratio (at each end).

>Would I then also have to choose it according to my operating frequency?
>That would mean that, for a different band, I would have to put in a
>different balun?

Depends on the design used. The broadband ferrite ones would probably cover several bands. Tuned transformers or transmission-line transformers are indeed frequency-specific.

>Also, what would I have to watch out for in terms of voltage and current
>ratings? Does current flow on the antenna side of the transformer?
>Also, suppliers like DigiKey make the distinction between
>power-transformers and audio-transformers. What should I be looking for?

Digi-Key doesn't make anything appropriate. Power and audio transformers are both low-frequency units - designed to operate no higher than 20KHz or so. It won't pass much if anything at 144MHz.

With that radio I don't think you're going to have to worry about voltage and current ratings. The powers involved will be small enough to be no problem.

Yes, current flows on both sides.

Sure.... the equipped rubber ducky antenna is about the equivalent of a
dummy load. Any improvement over this is definitely a good thing. I have
the same one and with an external power supply it will deliver up to 6
watts.

>
> (2) I am very worried about damaging the radio. Are there any checks I
> can perform before hooking up my home-built antenna to the transceiver?

Connect an SWR meter to verify if the external antenna if within basic
tolerances. Most new transcievers have some sort or form of protection
against this but checking the antenna out cannot hurt.

> Has anybody ever built that one? How well did it work?

The simple "quick and dirty" antenna using a SO-239 antenna is a great and
cheap antenna. I just build one and it works great. With the max output of
this particular HT I have gotten over 30 miles with this antenna. Mounted
the SO-239 connector in the end of a 10 foot PVC pipe and mounted the other
end to a camera tripod and I have a wonderful portable antenna. (the
tripod's head was broken off before I got it.)

I didn't use one, and had no problems. Absolute highest SWR at any point
was barely reaching a 2 to 1. Make sure to use the 50-52Ohm coax though.

Only building codes maybe. Make this into what is called a Vent-tenna. Use
a coupler to attach it to the "stink-pipe" coming thru your roof.

Good Luck.....

I use a 400w DC to AC inverter and it seems to work fine for me. (usually around 99bucks) I have utilized both the laptop and the desktop pc and monitor on this. Never even got over a little warm. I did however use a direct connection to the battery. I have a cord with two clamps similar to a jumper cable on one end and the female cigarrette lighter socket on the other end. Have used this in field day and other similar type of activities.

> > 150uH coil (Q=50)

Are you sure that you measured the Q for each individual inductor at the intended final operating frequency ?

The inductive reactance is obviously frequency dependent, but so are the resistive losses. Skin dept is inversely proportional to the square root of frequency, thus reducing the effective cross section of the conductor and hence increasing the resistive losses with frequency. For core materials other than air or vacuum, the core losses have some frequency dependency. Thus, it is very important to measure the actual effective series resistance of a coil at the intended frequency and not rely on figures obtained from tables or manufacturer data sheets that may apply for quite different frequencies.

However, the Q=650 for a 1.8 mH coil at LF sounds quite optimistic. Is this an actual measurement at 150 kHz ? Where is the parasitic resonance of that coil ? It appears as if the measurements are taken close to the self resonance frequency, in which case the distributed capacitance between the turns form a parallel resonance circuit and close to resonance, the combined reactance can be much higher than the inductive or capacitive reactance alone and thus, the apparent Q might be quite high.

To calculate the Q of the two coils in series, in addition to calculating the combined inductive reactance and resistance, you also have to calculate the resulting combined distributed capacitance and from that the capacitive reactance, combine the parallel connected inductive and capacitive reactance and calculate the Q by applying the series resistance (losses).

Martin,

>I abandoned my initial designs and am now
>using a very simple design
>that uses 4 diodes. The ARRL Handbook
>calls this arrangement "diode
>double-balanced mixer".

With such a mixer it isn't possible to build an AM transmitter. This is due to the fact that an AM signal requires a carrier that in this case unfortunately ;-)) is suppressed by the balanced mixer. You need to apply quite a different modulator design. If you need one, send me an e-mail.

>Question #3: Does what I see on the scope
>indicate that I am not modulating the carrier enough?

Not easy to decide without a picture. Could you take a photo of your scope's screen and put it to a website or e-mail it? It would make it easier to discern the potential problems you are facing.

>Question #2: what should the signal look like?

Look here

http://www.peter-rachow.de/amsignal.jpg

This is a photo of an AM carrier modulated to a degree of 100% by a single sine wave audio frequency.

>Question #4: What kind of an antenna could I
>hook up to my circuit? At a
>frequency of 1MHz, the signal's
>wave-length doesn't seem practical for
>the methods outlined in the Handbook.

Depends on the distance you want to hear your signal. Within your house a ferrite antenna could be sufficient. If you want more, a wire antenna is recommended, but you must have a lot of space for it. Medium waves are not to be covered with handy antennas ;-))

>Question #5: I am a bit confused as to what the
>power-ratings for radios mean.
>If I say I am transmitting at 5W power, what
>does that really mean? Does the standard:
>P=V*V/R still hold? In the standard case of

>dealing with a 50 Ohm antenna, does that
>mean my final amplifier is outputting a
>voltage of +/- 15.81V across the antenna terminals?

Depends. The power of a transmitter usually is measured in the peak envelope power mode. That means with your oscilloscope's reading you can measure the voltage of the sine wave of your (unmodulated) transmitter. This is called the "peak-to-peak"-voltage (I hope this expression in English is accurate, I'm not a native speaker ;-)). You divide this value by twice the sine factor (1.41 * 2 = 2,82) an get the dc equivalent. Square it an divide it by the 50 Ohm antenna load impedance. That result is your power in watts.

So long.

Graeme,

Graeme Zimmer schrieb in Nachricht ...

[DBM]

>It is. In fact it is commonly done this way.
>It is only necessary to unbalance the Mixer
>by a controlled amount.

But, in fact, this isn't a DBM anymore. And, with deliberately abandoning the benefits of a DBM, other modulator designs give the constrcutor more advantages.

BTW, a (disbalanced) DBM must be switched in one of the pre-amplifier stages of the transmitter. But, due to efficiency (and simplicity) reasons it is a better idea to modulate the last stage of an AM transmitter. This means, keeping to these design guidelines, you can run all the pre-stages in class C mode and by this enhancing the efficiency of the whole system and e. g. keeping thermal losses small.

If you operate all the tx stages in class A mode (which will be neccessary if you modulate one of the low power stages of the AM transmitter to maintain linear amplification throughout all the stages) you will have a very poor input/output energy ratio (which is common for SSB transmitters).

I recommend a modulator applying an af transformer switched in the Vcc line of the AM transmitter's final stage. This circuit requires an af amplifier capable of delivering nearly the same power level as the rf amplifier stage. Benefit: The additional amount of input energy then increases the total output of the rf stage. Another solution could be a transistor driven by the audio frequency and like the transformer switched into the power line of the final rf stage.

Part of the reason that tube prices went up is due to fewer being made and
sold.
I saw this while working in my brothers TV repair shop.
6146's are much lower priced compared to those 6js6c's, at least on the web
site I had located by doing a search..
And, IMO, are a bit more durable.
Though I never used them to replace the 6js6c's...
Need to change the socket for that.

Yes, I know. I wish there was something that could be done but I guess it is the rarity of the tube that drives the price way up. I notice that almost all sweep tubes these days are high priced. Also, I guess they're not really meant for RF amplifier service and better suited for 70's televisions, which would also be a contributing factor. One often wonders why reputible manufacturers would have used them anyway as RF amp tubes. Cheaper at the time I suppose.

Just a few years ago, I probably had a dozen 6JS6's. Not thinking I would ever be going back to tube equipment, I practically gave away close to 500 tubes. Now, obviously, I'm seriously regretting my mistake!

I've always liked to troubleshoot and repair my own equipment. With tube equipment, I am quite the novice but I know this will improve over time. Earlier solid state rigs were challenging to repair, but I almost always managed to get them up and running again, at least 80 percent of the time. Today's modern rigs are beyond my capabilities to repair, especially with all the surface mount components involved. Therefore, I tend to avoid them but the door is then opened to earlier rigs. However, obtaining parts gets more and more difficult as the equipment ages. This Yaesu tube situation is a good example. It's unfortunate for those like me who like to keep older equipment functional.

BTW, I'd like to thank those people who provided several alternatives to obtaining the 6JS6C's at more reasonable prices. I intend to look into these further.

If I decide to convert to the 6146's, I'll post the results since there seems to be little feedback info. regarding this subject.

Thanks again and please continue to share opinions and experiences with the 6146 conversion.

I ordered from dan's 3 weeks ago myself, first time I ordered from him, have
been anoyed the last week, running to the mailbox every day, because I'm
waiting for some stuff, and 3 weeks is to long, how the hell can it take
someone 3 weeks to put some bags in a box, label it and put it in the mail.
Im' very glad also I've kept my part of the money order card, the ostal
office promissed me they would get my money back incase of any problems.
Didn't try to call, because a call to the states from here (belgium) is
quite expensive.

thanks for the replies

Posted the question by mistake and cancelled it immediately, but as
sometimes happens for some reasons I seem to get more replies when I
cancel the original post.....
I also found the formula (you know how quiet it is during Easter), but
thought it was easier to calculate the series resistances at a
frequency and add them to calculate the Q.

You can't walk around and remember all sorts of formulas and it is
very seldom you need this calculation, I haven't needed it before
constructing a 136kHz converter, where to coils were added in series.

The worst problem was to find a 20+50pF tuning capacitor, and I ended
up with connecting two FM sections together and removing rotor plates
from an AM section, hi. Tried to build a 60kHz xtal filter, but it was
difficult and spectrum analyzer was no help, but a two coil LC BPF
seems to be sharp enough

I realise this, but such has not always been the case. People in general
weren't so greedy and money hungry until just a few decades ago, and were
more willing to give things away to those in need. It's not so much that
people nowadays want money for their goods, but rather the outrageous profit
margins that perpetually rise because of "lack of availability" and the lust
for money on the part of those who hold us in virtual consumer slavery..

Example: I *used* to collect coins as a *hobby*. Why is it that when a new
commemorative coin such as the Susan B. Anthony or Eisenhower dollar, the
Kennedy half dollar or the new state quarters are issued, the yuppie idiots
immediately run down to the banks and buy hundreds or thousands of them to
stick up in a closet and sit for decades, and save *every* single one that
they get in change, thus limiting the legitimate collectors of the pleasure
of finding and/or affording them for their hobbies? The same can be held
true for vintage ham radio equipment, parts and accessories..

I'm from the old school when people put more value on kindness, reason and
human compassion than riches, and i'm not at all impressed by what I see
nowadays. There are entirely too many selfish people in the world today..

Hey Peter-

Thanks so much for your reply. It is greatly appreciated.
I do have a few more questions and would love to hear your input if you have some more time:

Peter Rachow wrote:
> With such a mixer it isn't possible to build an AM transmitter.
> This is due to the fact that an AM signal requires a carrier
> that in this case unfortunately ;-)) is suppressed by the
> balanced mixer. You need to apply quite a different modulator
> design. If you need one, send me an e-mail.

Couple of questions:

(1) What would a diode mixer like that be used for then?

(2) I was under the impression that suppressing the carrier was a good thing to do in AM transmissions. It means that you don't have to waste power on the carrier, which doesn't really carry any information anyways (Please(!) correct me if I am wrong).

(3) Yes, please, I'd love to see a different design. Feel free to e-mail it to me directly at martin@cyclotomic.com
Thanks!
I got some feedback from the people in sci.electronics.basic and have seen some other designs already, but it can't hurt to see another one.

(4) If a carrier is always necessary, what about single-sideband suppressed carrier transmissions?
I thought the name implied that the carrier signal was not present in the output anymore?

> Not easy to decide without a picture. Could you take a photo of
> your scope's screen and put it to a website or e-mail it? It
> would make it easier to discern the potential problems you are
> facing.

Yeah, I know that without a picture one can't really tell. Sorry everyone :(
Unfortunately, I do not have a digital camera, so I don't think it could get that done in a timely manner.
But looking at the image you put up on your page (thank you!), it is quite clear that mine doesn't look like that and that I am still ways away from my goal :)
No problem, though: it's always fun to learn.

I'll wait to hear from you regarding the diode mixer there, but I do have one question I can ask already: would any and every AM-modulated output wave-form look like the one you posted on your site? Regardless of the type of modulation (i.e. DSBFC, SSBFC, SSBSC)?

> Depends on the distance you want to hear your signal. Within
> your house a ferrite antenna could be sufficient. If you want

> space for it. Medium waves are not to be covered with handy
> antennas ;-))

OK, very silly question: what exactly is a ferrite antenna? Are we talking about turns of magnet-wire around a ferrite core? Similar to what they use(d) in (old) radios?

Thank you again for your feedback.
Congrats on your book, btw! I checked out your web-site and saw the reference to it. Very neat.

If it's easier for you, feel free to reply to my e-mail address in German.

Martin,

Don't pay any attention to some of the sarcastic remarks. Some guys think that they are radio experts and think that the ham license makes them that. There are many levels of understanding of radio. You are doing the right thing by trying circuits and asking questions and reading the books.

As far as your double balanced mixer goes that is the heart of an SSB transmitter or a double side band suppressed carrier transmitter. You can generate a regular AM signal (double side band with carrier) with the same mixer. The only difference is that you have to apply dc bias to the diodes to unbalance them so that you have carrier. Then applying modulation you will get a signal just like the broadcast band AM stations. If you remove the bias so that the modulator is again balanced you will have double side band suppressed carrier signal. In order to demodulate it the receiver has to re-insert the carrier.

SSB is generated in the same way as double side band suppressed carrier. But following the balanced modulator a sharp filter is used to filter out one of the side bands. Now you have SSB suppressed carrier. Again in order to demodulate it in the receiver you must re-insert a carrier in the receiver. If you now unbalance the balanced modulator so that you have some carrier you will have a single side band AM signal (with carrier). No need to reinsert the carrier at the receiver because it is being transmitted.

I do agree with one of the other posters though as far as a simple AM transmitter, you may be better off with a transistor amp being modulated by a transistor.

You are so right. But you can't give up, there are still quite a few of us old school guys out there. I gave away a Radiotron Designers Handbook a couple of years ago to a youngster that said he'd learn from it. At the time, I didn't know they were fetching $100.00 and up on eBay. I got lots of requests asking if I had another one, and wouldn't you know it, I found two more. What did I do? I gave them away to the first two that convinced me they would actually use them. We all still correspond.

I believe the knowledge and goods we have are a gift, intended to be shared. I know there are lots of people that don't feel that way, but I don't have to join them.

Commercial or home-built (you did post in the homebrew group...).

http://sproggy.mp3car.com/psu.html has a progressive design. Lots
of good stuff for your task there under the mp3car.com domain...
Also see 12voltmp3.com

Here is another homebrew: http://cybersake.www.cistron.nl/carmp3/

And if you want commercial, be willing to pay. Rack mount folks
like cyberresearch.com could probably provide. Or check out
http://www.keypower.com/DC_power/DX-250H.htm

It's called free market capitalism, where the demand regulates supply. If there are a few items many people want, prices will go up. It's a beautiful concept when you think about it. So simple and natural.

> Example: I *used* to collect coins as a *hobby*. Why is it that when a new
> commemorative coin such as the Susan B. Anthony or Eisenhower dollar, the

Because they know that years later collector idiots will pay good money for shiny quarters no one bothered to save when they were widely available?

> The same can be held
> true for vintage ham radio equipment, parts and accessories..

The solution is simple: we have to establish a Central Committee which will nationalize all the vintage ham radio equipment and which will then redistribute it according to the needs of the people.

> I'm from the old school when people put more value on kindness, reason and
> human compassion than riches, and i'm not at all impressed by what I see

Bullshit. This is nothing but geezers' cry about the good old times. It's never as it used to be - it was always better when we were young, wasn't it? Even when there was slavery, tyranny, plague, no elections, no electricity, no food, no fire...

2526. SL6440 as modification to HF transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-03 00:22:50 UTC
From: la8ak.xnd@online.no
Message-ID: <3caa4855.27665211@news.online.no>
Source record: 45117

I am promissed some SL6440 devices and wonder if somebody has
experience in replacing other ringmixers with this device.
FT-902 has a ringmixer of unknown data, but IP3 isn't particularly
good so I wonder if it is easy to use SL6440 instead without too much
problems. FT-902 also has a J310 buffer amplifier, but I am not
certain if it is really 50 ohm.
-1dB gain for SL6440 is 6dB better than any schottky diode ring mixer.

Thanks to all contributors. I finished the 136kHz converter project. The 40673 1st converter with IF filter has power gain of 47dB, I am surprised! Used an S042P as second mixer, IP3 products seem not important as it is 0.5kHz bandwidth filter ahead of this mixer, it converts from 60kHz to 3.5MHz. Only problem is that balance for S042P could be better, so I must check up later. Also injection to 40673 is low and should be increased from 0.2 to 0.4V RMS to be optimum according to RCA manual.

Will study the received material later.

Source record: 45119

You say," With some help from sci.electronics.basics, I believe I finally got rid of the notion that in AM, the carrier's amplitude is changed over time."

But it is! Let your DSB amplitude modulation frequency be 1Hz.
Your carrier will vary from 0v.pk.-pk. to 2 times unmodulated carrier voltage. At the same time, this is also an unmodulated carrier, accompanied by two side-bands at the carrier frequency plus 1Hz and at the carrier frequency minus 1Hz.

The three frequencies reinforce and cancel at periods of one second.

Both ways of looking at the thing are equally valid. They are just two ways of expressing the same thing. If you displayed it on an oscillograph with a slow time-base, you would see the carrier wave as a fuzzy area increasing and decreasing at 1Hz. If you had a sufficiently selective receiver you would detect three frequencies at Fc, Fc+1 and Fc-1.

To generate A.M. you need a circuit whose gain can be varied at the modulating frequency, which is effectively what your unblanced diode bridge is.

Does this help or confuse?
Regards, G3CCL.

OK.
Thanks for pointing that out.
I went back to my text-book and found what you are describing in there
as well. Along with a nice diagram showing how the different waves would
add (they illustrated this concept using phasor addition, showing the
LSB, USB, and carrier components).

This is slowly starting to make sense...

Now, theoretically, is the carrier's amplitude really varied by the
modulating signal? Or does the output wave-form's amplitude vary
depending on the modulating signal?

My text-book says that the voltage distributing in the output wave-form
would be:
Vam(t)=(Vc+Vm sin(2 pi fm t)) sin(2 pi fc t)
i.e. that the carrier's amplitude does not depend on the modulating
signal.

> To generate A.M. you need a circuit whose gain can be varied at the
> modulating frequency, which is effectively what your unblanced diode bridge
> is.

This how I started to approach the issue at first, but with no luck.
I tried hooking up a simple BJT amplifier circuit using an NPN
transistor. I fed the modulating signal into the transistor's base and
connected the transistor's collector to the circuit generating my
carrier.
I couldn't get that to work in either real life or in Spice.
Is that the idea, though? Is that one way to generate AM modulated
output?

My text-book shows a circuit where they reverse this setup, i.e. feed
the carrier into the base and "couple in" (correct word?) the modulating

signal via a transformer, fed into the circuit at the emitter. The output is taken at the collector (with a resistor to the supply) and high-pass filtered with a simple RC stage to get rid of the modulating signal's frequency components.
The only explanation they give of the circuit is that because it is operating nonlinearly (either in saturation or cutoff), modulation is performed.
Why would it be operating in either saturation or cutoff? Because the voltage level at the emitter is raised or lowered? I.e. brought up so high that the base-emitter junction is not forward-biased anymore and so low that the collector voltage is pulled down to within -what was it again?- of the base-voltage?
Now, assuming that it does operate in either saturation or cutoff, why would that perform modulation?
The output wave-form they show looks like the carrier signal added to the modulating signal (i.e. the carrier signal superimposed on the modulating signal).

I guess I'll go back and try that circuit again in Spice and on the breadboard.

Thanks again for your post! It did make things a bit clearer.
Thanks!

Hello Gary-

Thanks for your detailed reply.

Gary Schafer wrote:
> AM signal (double side
> band with carrier) with the same mixer. The only difference is that
> you have to apply dc bias to
> the diodes to unbalance them so that you have carrier. Then applying
> modulation you will get a

Great! I had read that in one of my text-books, I believe, and it even kind of made sense.
I looked at how the diodes would switch for the input signal and understand why the output wave-form looks the way it does.

> I do agree with one of the other posters though as far as a simple AM
> transmitter, you may be
> better off with a transistor amp being modulated by a transistor.

OK. So could I build a simple transistor-based (I am most comfortable with simple NPN BJTs) amplifier that amplifies the carrier depending on the modulating signal?
Would that mean that I feed the modulating signal into the transistor's base and the carrier signal into the transistor's collector (all with appropriate DC offsets, of course)?

Another thought I had (I haven't had time to experiment) would be to setup an amplifier where I feed the carrier into the transistor's (Q1) base and connect another transistor's (Q2) collector to Q1's emitter.
The modulating signal would be fed into Q2's base.
The second transistor would then control the current that could flow through Q1. If you took the output off Q1's collector resistor to Vcc, you would then have a signal that is changed in strength according to the modulating's signal strength, at the carrier frequency.
Would that work? Sorry if I am totally off with this one. It was just a thought...

Thanks again for your input.

Check out www.aesham.com they have a good selection. Ask for their catalog and that should give ya some good ideas as to what to purchase. First and obvious choice is make sure it is designed for the frequencies you wish to test.

Anything over the rubber ducky is an improvement. Check AES at the above listed website as they have some better antennas to replace the factory rubber ducky.

That antenna above and the ventenna are listed in the ARRL Antenna Handbook or the ARRL Handbook. Check them out or maybe someone else here has knowledge of a link to a website where you can find more. Both ARRL books

are good reference materials for your library though.

> Thanks again for your input!

Face it, the "Mail" SUCKS.....

I had a package sent to me from New York and it took a week to the day it was shipped. I'm only 300 miles from the origination - in PA. Then, I shipped a package 2nd day "Priority" to LA area. It took 2 weeks and 2 days to get there. Priority - my ass. I have a package coming from Alaska. The dogsled or Iceberg express must have hit a snag. It's been almost a month......So it may not be the shipper's fault. Blame the freaking Postal Service who wants "another" raise..... IF any of US failed to deliver according to OUR terms as they do, we would be busted. The BBB and any other agency would be down our throats..... I'm going UPS if I can help it, from here in - especially with anything with any amount of weight to it. I've never had any problems with them.

2538. Re: AM Transmitter project

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-03 08:24:04 UTC
From: Peter Rachow <peter.rachow@t-online.de>
Message-ID: <a8ef3g$s44$02$1@news.t-online.com>
Source record: 45129

Martin,

>(1) What would a diode mixer like that be used for then?

Generally it is used to mix to frequencies f1 and f2 so that you
can see two new output frequencies at the output of the mixer
device. These frequencies are:
- the summation signal of the two (f1+f2) and
- the substaction signal (f1 - f2 or f2 - f1 if f2 is higher
than f1).

Among all the mixer circuits that are common the DBM ensures the
maximum suppression of the former input signals at the mixer's
output side, so that (theoretically) only the new signals
appear. Generally it is used to generate a double sideband
signal if you mix an rf signal with an af signal. One of these
two frequencies later is filtered so that you get a single
sideband signal (SSB). Other applications for DBMs are

- Generating an intermediate frequency in a receiver
- Mixing a (e. g. 9 MHz) SSB signal to its destination frequency
e. g. creating a ham band signal.

>(2) I was under the impression that suppressing
>the carrier was a good thing to do in AM transmissions.
>It means that you don't have to waste power on the
>carrier, which doesn't really carry any information anyways
>(Please(!) correct me if I am wrong).

No, definetely not. ;-)) The carrier is required in the
reception process. An AM signal consists of three distinct
components that are emmitted simultanously:

- The AM carrier (fC)
- The upper side band signal (USB which is fcarrier + faudio)
- The lower side band signal (LSB which is fcarrier - faudio)

This is a bad idea if you take only the energy considerations.
But the AM carrier is essentially required for demodulation
because in the receiver there are mixers (sometimes DBMs) that
substract for example the fUSB - fC and therefore get back the
audio signal in its original frequency range. If there is no
carrier you cannot demodulate the signal.

>(3) Yes, please, I'd love to see a different design.
>Feel free to e-mail

OK, I'll look into my library. But some circuits are commented in German, I hope that won't confuse you. ;-)

>(4) If a carrier is always necessary, what about single-sideband
>suppressed carrier transmissions?

That's the main difference between AM and SSB. An AM signals transmits a fixed carrier frequency plus the USB and LSB signal. on the opposite the SSB signal consists only of a USB *or* an LSB rf signal. For the reception and demodulation process of an SSB signal the neccessary carrier is injected into a mixer (we sometimes call this mixer "product detector") in the receiver. And now the former signal (which during transmission had no carrier) has now got some sort of 'artificial' carrier and the process of frequency substraction can take place. Demodulation of an AM or SSB signal is nothing than a final freqeuncy substraction so that the resulting frequency spectrum falls into the audio band.

In general AM and SSB signals can be demodulated by the same circuits. But, due to the fact that an AM signal comes with a carrier, you do not need to generate an "artificial" one. And, another benefit of AM: In this case the carrier has got the right frequency distance to the USB (and LSB) sidebands, so that the resulting audio frequencies sound natural (If you do not take into account the restricted bandwidth that distorts the signal somehow).

>I thought the name implied that the carrier signal
>was not present in the output anymore?

In AM signal it is an *essential* component of the signal spectrum.

>I'll wait to hear from you regarding the diode
>mixer there, but I do have one question I can
>ask already: would any and every AM-modulated
>output wave-form look like the one you posted on
>your site? Regardless of the type of modulation
>(i.e. DSBFC, SSBFC, SSBSC)?

Not, the shape of the signal depends on the modulation you use. If we take the most simple case, we can modulate a one-tone-audio frequency to an rf carrier.

In AM the outcome looks like the picture I put on my web site (100% modulation degree). The shape you see is a result of the fact that 3 frequencies are present at the same time (fCarrier, fUSB and fLSB) and that they are shifted in phase by the audio freqeuency and are only 1/4 of the fCarrier voltage.

In SSB the result of modulating a single af tone is only one constant sine wave signal. This is due to the fact, that two new

signals are generated if we mix ONE rf sig with ONE af sig and
that one of the resulting signals is suppressed in an SSB filter
.

Using DSB modulation it might look like the AM signal but the
cross points in the center of the sine wave might look
different.

>OK, very silly question: what exactly is a ferrite

Source record: 45130

If I was going to replace a diode ring mixer, it wouldn't be with a 6440; I would used something like the Siloconix SD5400 series of Quad JFET mixer. The IP3 would be better than either the diode ring type or the 6440, unless a Level 17 or Level 23 type of ring was used.
The 6440 was a pretty good device, but it required a fair amount of external components.

Negative, you will probably need a good transciever and a linear amplifier.

Martin,

>My text-book says that the voltage distributing in the output
>wave-form would be:
>Vam(t)=(Vc+Vm sin(2 pi fm t)) sin(2 pi fc t)
>i.e. that the carrier's amplitude does not depend
>on the modulating signal.

That's correct. I've posted another picture showing how the 3 distinct frequency in an AM-signal are added to the typically looking AM frequency graph. A (not shown) 2 kHz "af" ist modualted to a 10 kHz "rf". The resulting frequencies are 10 kHz (the former carrier remaining uninfluenced) and the fUSB and fLSB sig. By simply adding them to a voltage summary signal you get the shape of the modulated AM sig.

See http://www.peter-rachow.de/amsignal2.jpg

>Now, theoretically, is the carrier's amplitude really
>varied by the modulating signal? Or does the output
>wave-form's amplitude vary depending on the
>modulating signal?

As mentioned above: The carrier is not varied (neither in frequency than in amplitude) by the modualting frequency. It is once used to generate the side frequencies and then not more requiered (theoretically) in spite of the demodualtion problem (see my other posting).

>This how I started to approach the issue at first, but with no luck.
>I tried hooking up a simple BJT amplifier circuit using an NPN
>transistor. I fed the modulating signal into the transistor's base and
>connected the transistor's collector to the circuit generating my
>carrier.

That's one way you can do it. A good approach for a working curcuit could be the following:

- Build a simple CW transmitter from the ARRL handbook with 2 or 3 stages (stages counted including the oscillator).
- Lead the +Vcc line of the last amplifier stage through a simple switiching (i. e.modulating) transistor that is fed (to the tranistor's base) with the audio frequency you want to modulate. Be sure to bias this transistor in an appropriate

manner. That means that you should supply a constant base current via a variable voltage divider to the base of this modulating transistor. You must in every case check the modulation with an oscilloscope.

I posted a circuit sample under

http://www.peter-rachow.de/ammodcircuit.jpg

If you ever visit Europe there's a good alternative from PA0SSB in Holland.
He offers a nice full coverage, 100W HF kit for reasonable prices. But I
guess he won't send it to you since the shipping costs will be as much as
the price for the rig itself and he wouldn't be able to offer you after
sales service. You can see the picture of the designer and the rig itself on
the next link: http://home.pi.se/sm0fly/pa0ssb.htm
good luck 73

Funny how differant things take differant times. I ordered a 17 inch monitor a couple of weeks ago and it only took it 3 days to get here from about 250 miles. Thing about it is it went within 10 miles from the house to a place about 40 miles away to a hub then back to the local UPS depot and then to the house. I have usually had good luck with the shippers as most of the time it is a call to order on Munday morning and the item is here by Friday if the item is sent to the UPS or Fedex that day.

Since when is caring about other people instead of $$$ a bad thing?? I realize it has fallen largely out of vogue, what with the egocentric society that pervades these days. Life itself, let alone one's fellow human beings, has become virtually worthless.. a throwaway commodity, like a used razor... I don't know about you, or anyone else, but this scares me to death. I'll stick to the old ways, where people matter. If ever comes a time where money takes precedence in my life over another human being, it will be time for me to make my exit.

Take care, and stay well.

Martin,

I was not offended by what __you__ said.

My comment was directed at the __previous poster__ that suggested that
it was an April Fool's joke.

I thought the same thing when I read the problems that you were
having, and then saw that you __did__ have a ham license. It made me
wonder if maybe it was an April Fool prank.

I know it has been a long time since I took a license exam, but I
believe they still require some knowledge about how radios work, don't
they? And basic schematic reading?

Well, to be honest, most tubes are easy to get. Pretty much all the standard audio tubes are in current production, compactrons and most other TV tubes are a glut on the market, and most standard radio tubes have supply greatly exceeding demand.

The problem are some of the more obscure tubes, and sweep tubes.

And sweep tubes are a special case, and the worst possible case, and they are the problem with the FT-101. Because they were dirt cheap, designers used them (and lots of folks converted commercial gear to use them). TV set tube production was very high and there were plenty of sweep tubes out there.

Then tube TV sets stopped being made, but there were still huge numbers of sweep tubes in the warehouses.

The problem came with appliance operators who didn't know how to neutralize their finals, people who ran the finals at outrageously high levels, and the illegal CB linear crowd who often ran huge numbers of badly matched parallel tubes.

And these people collectively destroyed most of the stock of sweep tubes out there, and now they sell for outrageous amounts of money. THAT is the problem more than anything else. Tubes that should have lasted for years of operation that only lasted for hours.

Melissa...

Elecraft is about to introduce a 100-watt output amp for the K2 transceiver. It is in beta test now and I'll bet shows up for sale at Dayton. It will be built into the top so won't increase the size at all, and becomes an integral part of the radio. If you want to go back to QRP, just pull the amp and reinstall the original top which contains the battery and auto-tuner options. Takes about 3 minutes to make the change. (There will be an autotuner for the AMP as well.)

Also, bear in mind that the K2 has a receiver that will compete with the best commercial rigs available today... **WAY** beyond Heathkit's wildest dreams. The ARRL said it handles close-in QRM better than ANY receiver ever tested in their lab.

THE K2 IS NOT YOUR "TYPICAL" KIT RADIO! In A/B comparisons, I have never heard any station --under any conditions-- on my IC-756PRO that I couldn't hear at least as well on the K2, and I have been able to copy a few on the K2 that were unintelligible on the PRO. And the PRO heard a few I couldn't pull out on the FT-1000D I used to own.

The K2 feature set is outstanding and it's fun to build.

OK. So I did get the concept. Thank you for explaining it again.
I believe I used the terms amplitude modulation and SSB interchangably
and that's where my confusion stemmed from. Thanks for clarifying.

> OK, I'll look into my library. But some circuits are commented
> in German, I hope that won't confuse you. ;-)

No problem at all.
As long as it's in English, German, or Spanish I'll be able to deal with
it.
Feel free to e-mail me the schematics directly at the address below.

Thanks for the explanation regarding the differences between DSBFC and
SSBSC transmissions.
I merely used the same term (amplitude modulation) for both, and that's
why I was confused when you said that a carrier was always required.

> In AM the outcome looks like the picture I put on my web site
> (100% modulation degree). The shape you see is a result of the

Oh goodie! Thanks for explaining that! That's what I thought, but I
wasn't sure.
That makes a lot of sense, thank you very much!

Thanks again for your reply. If you do have time and find another
schematic or two, I'd love to take a look at it.

> However, the Q=650 for a 1.8 mH coil at LF sounds quite optimistic.

Sounds like a loop antenna to me, maybe 2 meters on a side, square,
wound with 3.5mm diameter wire...or something close to that. It is
rather a lot of wire. But Reg's loop3 program, at least, predicts Qs
up in the 650 range for such a loop at 150kHz.

(It makes me wonder what the Q of the "helix" loading coil used at the
Jim Creek 20kHz transmitter is...)

Cheers,
Tom

I'll go back and try that approach again.

> http://www.peter-rachow.de/ammodcircuit.jpg

Thanks for posting that schematic.

Last night I finally got around to trying the circuit I had described previously: I connected the carrier signal to the base of a NPN amplifier circuit. The modulating signal is connected to the emitter, and the output is taken at the collector. The amplifier is biased at the base with a voltage divider, and has a series network of resistors in the emitter for gain; for stability, one of the emitter resistors is shorted out at higher frequencies by use of a capacitor. The voltage at the collector is set to 1/2Vcc under DC conditions, assuming 0.5mA.

The circuit does work: I can pick up the signal with my radio.
However, the output signal does not look like I thought it is supposed to (I think). The spice simulation also shows a different output wave-form from what I am measuring with the scope.

I had totally forgotten that I have a web-cam sitting around here somewhere.
The quality is terribly (sorry), but at least I have some pictures up of what I am dealing with at least.
You can find the pictures, as well as a schematic and Spice input at:
http://www.cyclotomic.com/~martin/ammod.html

Any input would be greatly appreciated.

Thanks-

Martin

Hi Martin,

I took a look at the pictures on your web site and the oscilloscope readings look very familar to me. They're just bringing me brack to my old radio days ;-))

One that I recognize best is entitled "Measured output (wave-form at bottom is the modulating signal)". The problem in this case is, that the modulation transistor does not perform properly. This can be due to several reasons:

The most probable in my opinion is the following: If you use the circuit that is printed as the first image of the page, I can imagine where the cause for the faulty performance lies: You put in Vmod at the emmitter of the rf transistor and bypass it with the RC-combination 0.1u/100 Ohms. That is not a good idea because the transistor can get direct current from the ground line and so bypasses the modulator transistor or whatever you have there. The waveform that I can see on the picture is not AM, it looks like some sort of incomplete superposition of two different sine waveforms.

BTW: I faced similar problems about 20 years ago, when I started to build tiny AM radio-control transmitters for the 27 MHz band that were modulated with sine waves. The modulation circuit I ended up with (because it was the most reliable and best performing one) was that, which I posted on my website. In oder to enhance the modulation quality you can also lead the power for the pre amp over the modulating transiator so that two stages are modualted. This ensuees a much more accurate modulation if the bias for the mod transistor is set properly. Sometimes I used transformers instead of a transistor but that required an audio power level in the range of the transmitter's rf output. But once this was granted, these curcuits worked well, too.

To point it out again: If want to have a proper amplitude modulation you must lead the *whole* current of at least the final stage of your transmitter thru the modulating device. It is even more recommended to co-modulate also the stage in front of the final stage. But, you should not modulate the oscillator, this might lead to unwanted FM.

In our school library we've got some of the older books dealin' with AM radio control transmitters. Unfortunately this week there is no school because I'm on holiday. If you drop me an

e-mail by the beginning of next week, I'll remember to check out
some literature on this specific topic.

Martin,

I took a look at the pictures on your web site and the oscilloscope readings look very familar to me. They're just bringing me back to my old radio construction days ;-))

One that I recognize best is entitled "Measured output (wave-form at bottom is the modulating signal)". The problem in this case is, that the modulation transistor does not perform properly. Or, to say it more claerly: It does not modulate the rf stage at all. This can be due to several reasons:

The most probable cause in my opinion is the following: If you use the circuit that is printed as the first image of the page, I can
imagine where the cause for the faulty performance lies: You put in Vmod to the emmitter of the rf transistor and bypass it with the RC-combination 0.1u/100 Ohms. That is not a good idea because the transistor can get direct current from the ground line and so bypasses the modulator transistor or whatever you have there. The waveform that I can see on the picture is not AM, it looks like some sort of incomplete superposition of two different sine waveforms.

BTW: I faced similar problems about 20 years ago, when I started to build tiny AM radio-control transmitters for the 27 MHz band that were modulated with sine waves. The modulation circuit I ended up with (because it was the most reliable and best performing one) was that, which I posted on my website. In oder to enhance the modulation quality you can also lead the power for the pre amp over the modulating transiator so that two stages are modulated. This ensures a much more accurate modulation provided the bias for the mod transistor is set properly.

Sometimes I used transformers instead of a transistor but that required an audio power level in the range of the transmitter's rf output. But once this was granted, these curcuits worked well, too.

To point it out again: If want to have a proper amplitude modulation you must lead the *complete* current of at least the final stage of your transmitter thru the modulating device. I want to help by re-enforcing the notion that the 'carrier' with 'sidebands'
concept is a FREQUENCY or FOURIER domain concept. The notion that the
carrier is modulated by varying it's amplitude is a TIME domain concept. It
is easy to be confused (for a beginner) to mix the TIME and FREQUENCY
metaphors.

Hi,
I can obtain 433Mhz TX/RX modules specd as:
TX RF out 10mw max.
RX sensitivity -100 dbm
See http://www.aurel.it, 400Mhz audio transmitter/receiver modules.
I would like to know what range I could expect of this pair.
Furthermore, both antennas need to be 50 ohm.
What kind would this be, and what would the required length be?
My application calls for a minimum of 100 meters distance with a
simple wire antenna.
Any help much appreciated.
Thank you
Johan Smit

My initial thoughts are the 10mW would handle the job - but only just - however it will depend on where they are being used and whether the units are AM, FM or "QM" - sort of a mix of the two. If the unit is FM or QM, then if the units have little between them, I think you will find reasonable results. However for AM operation, you will almost certainly find operation at 100M difficult if not unusuable.

If the modules (FM/QM) are mounted 100m apart in an open field you should find things work spinningly well - all things being roughly equal - in practice, this is rarely the real-world application.

If the tx is housed in a basement, while the receiver is in another basement 100M down the road, then I guess you'd be lucky to get through with over 10 times the power.

Also, when you say "calls for a minimum of 100 meters....", do you mean this is the minimum acceptable performance - or do you mean in some applications it will need to work at distances greater than the minimum? If the latter, then what is the *maximum* range these units will have to contend with?

Lastly, I guess the amount of electrical / electronic noise is important too. If you operate these units and someone else has something similar operating nearby, you may have interference. Likewise if someone in the area has an electrically noisy photocopier etc, this may also give the receiver some unwelcome fun to handle - espceically if the signal is only just getting through in the first place. Is this acceptable?

My experience with RF is VERY limited - however I have played around with 433 and 418 modules a little - and (IME) the range can vary HUGELY depending

on the factors mentioned above. Some of the more learned posters in the ng
may be able to give you much more useful information. However, whoever tries
to help, it would be useful to know the following please.

Modulation type (AM/FM/QM) (perhaps even part numbers?)
Type of use: / continuous / pulsed / encoded data / voice / etc
Positioning (outside/inside/underground/mobile etc)
Is a "noisy" but readable signal acceptable or not.
Is loss of signal a MAJOR issue if only occasional.
Is performance or price the biggest issue - if you HAD to choose?
Is 433 @ 10mw the only acceptable solution?
Are you adamant that the RX must also use a whip?

Mark

Believe it or not, there are still places left in this world where people leave their front doors unlocked, even when no one is at home. I used to work in one of these areas, which is a small semi-rural community where everyone knows everyone and trust runs high among the locals. When people made appointments for me to come over to their houses and they couldn't be home, they would just say "the door is unlocked. He knows where and what needs to be done. There's a beer/soda pop in the refrigerator. Just tell him not to let the dog/cat out and pull the door shut when he leaves..

I knew a lot of the people on a first name basis, the dog in the backyard, seen people's hidden contraband, marijuana plants, etc, and virtually had free run of the whole doggoned area, pasturage, wooded areas, etc without having to worry about getting shot at for wandering into the wrong place..

Because my boss was a jerk, I left that job for another one "over the hill" in "civilisation" which offered a very substantial increase in pay, but I still miss the people and the laid back and virtually stress free work atmosphere which I had held onto for five years because in many ways it was worth more to me than all the money in the world..

Yep. Sometimes simply throwing in a low resistance (5 or 10 ohm) carbon film resistor will upset whatever tendency for oscillation you might have. The film resistors have a bit of inductance, plus the resistance, so its a cheap parasitic choke that has little adverse affect on the operation of the ckt.

Bill,

[SSB-Transmitter]

Is the TX constructed in that way that you use

- a TX mixer
- 3 pre driver stages (two 2n2222s and a MPF102)
- 1 driver stage
- 1 final stage?

If so, my first imagination is that your transmitter is working unstable and produces parasetic signals anywhere in the LF or VHF bands....

BTW: What does "Manhatten Style" mean?

Yep. Beta rises with temperature. This is what causes classical
thermal runaway in transistors (both bipolars and vertical power FETs),
and why amplifiers sometimes have to be temperature-compensated to keep
their idling current down to reasonable levels.

> Any ideas on what is happening and how I could stop it?

Just as a first guess, how about ferrite beads on the base and/or
emitter leads?

2568. Problem w 17m HB SSB TX

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-04 07:25:55 UTC
From: n2cqr@clix.pt
Message-ID: <3cabffda.2732497@news.clix.pt>
Source record: 45155

I've built a 17 meter SSB transmitter. I borrowed bits and pieces of circuits from various designers. The core of the sideband generator comes from a G3YCC article in SPRAT 48. Of course there are also elements from W1FB in there. The rig is built Manhattan style on a number of separate PC boards. The boards are mounted on the chassis of an old DX-40. The filter and the carrier oscillator rock come from a Swan 240 that got too clse to a lightning strike in the Dominican Republic. So the rig has some character!

I found that the hardest part of getting this one to work was the RF amplifier. I had to try several circuits before I found one that I could get stable. I now have two MRF 476s in parallel driven by a 2N3866. There are two 2n2222s and a MPF102 in the chain before the driver. The thing puts out about 5 watts PEP. Everyone says it sounds good.

Here's my problem: As the transistors start to get warm, I can see on my SWR bridge that there is some sort of low level signal in there -- it looks like just a few milliwatts, but it doesn't belong there. It persists even when I shut down the carrier oscillator. It is not at 18 Mhz. It shows a very high SWR into my 17 meter dipole. It is only there when the temp of the final goes up. I'm not sure what the freq of this spur is.

I've tried increasing the size of the heat sinks. This helped a bit. I suppose I could put a little CPU fan in there to keep the temp down, but I'm thinking that there might be a more elegant way to solve the problem. Also, I'd like to understand what is going on. Could it be that as the temp rises, the gain of the device increases making spurs and parasitics more likely?

Any ideas on what is happening and how I could stop it?

Maybe that exists somewhere now, but the current risk is that the same openness will have you sitting behind bars when some doper whines to the police that you stole his dope. Did I say risk? That was a risk 20 years ago...its almost a norm these days that a serviceman left in the house has stolen something.
I hitchhiked the whole country in those days...I wouldn't dare hit a highway now. Things have indeed changed and thats a sad comment on our society. Its a great memory, tho.

>Any help much appreciated.

You can accommodate 110dB nett path loss, from your +10dBm Tx to your
-100dBm Rx.

Free space pathloss at 433MHz over 100m is 121.2dB.

You will need to pick up that extra 11dB plus an allowance for cable
loss and path absortion by stray objects.

In simple terms, not practical unless you plan on high gain antennae
at BOTH e nds of the path.

Hi Bill,

Agree with previous observations.
Sometimes a (relatively) low value resistor with short to *no* leads from bases to ground can help. the tradeoff is that the bias circuit will need to supply more current and the effective gain of the stage is reduced. Another possible help is a "lossy inductor" in collector supply. ...Several turns on a FT43 core shunted by a 5-10 ohm resistor - like the parasitic suppresssor in a tube amp. At leas it is low level. I had some pop on at near full output (not used on the air!).

> N8EE

Hi Jim,

I just took my test about two years ago for novice. Yes you do need some basic knowledge but not much. Block diagram stuff for the radio part and the ability to distinguish between cap, resister, transistor, and inductor schematic notation is about it. The rest of the test is on rules, safety, band allocation and other such things. From what I've seen of the General and even Advanced question pool the actual technical side doesn't get much tougher than that need for a novice or Tech license.

That aside I can totally identify with this fellow. I have a masters in physics and I've been designing computers for 12 years now, I'm no dummy. But when I first started learning about radios I had to learn out of ARRL books and off the internet and I am amazed at how much information I thought

I learned only to have to relearn it when I realized I had misinterpreted the information. When you don't have an Elmer to answer questions, it's tough to assimilate that much new information and understand it all.

But this guy is doing the right thing, he is building the circuits and scoping them out and getting his hands dirty! We could use more hams like him. It is what I did and now I'm on the air with an HB 100w tube CW transmitter and an 8 tube HB Super heterodyne receiver that I designed and built myself. I laugh now at some of the notions that I formed when I first started but I got better.

Indeed -
Greenlee are the best - especially the "slug buster" kind.
Grainger has them and they supply spareparts too.
BUT if you do few jobs it might not be worth to spend the money.
You might get some bargain chinese punches. Mine are older
than 20 years and still do a good job.
Of course I wouldn't trust them for anything which earns the
butter on my bread.
Even Greenlees have to be handled with care, however. Especially
the small sizes. But you know this already...
You might also consider to get some step drills. Two
sizes might be sufficient for all your jobs. For AL they provide
faster working than punches. OK with steel too but slower.
Step drills or "Drill-Tree" mfg: VERMONT AMERICAN
goes from 1/8" to 1/2" and 1/4" to 3/4". JENSEN, Phoenix has them
but there are cheaper sources.
Then there are UNIBIT step drills. 4 sizes. TIME MOTION TOOLS.
I guess that Northern Tools or Lowe's has them too.

Regards, Ike

Rick,

Congratulations. It's a great feeling isn't it? All my stuff was homebrew for many years, and some of it still is. In the beginning, I built it because it was all I could afford. But I found out it was so much fun building and tinkering, I continued long after I could afford to buy commercial gear.

I still run an all vacuum-tube HF station. Running the transmitter is like driving a steam locomotive - lots of stuff to keep adjusted and if you don't pay close attention, BOOM. Single knob tuning? Bah! One of my old transmitters used to have nine circuits to tune between the VFO and the antenna - that was fun!

Hi Don,

Try http://www.triodeelectronics.com Ned, the guy that runs the place, has a whole set of 5 punches that will work dandy for most tube sockets, etc. The set is priced about the same as a single Greenlee punch. It's not as high quality as a Greenlee, but will do the job. The set doesn't go large enough for most meter movements I've seen. But it will go large enough for octal sockets and the like.

Ned's one of the good guys. Caters mostly to the tube DIY audio and guitar amp crowd, so he's got lots of tubes and other parts you might need. Very little SS stuff, though.

Best regards,

Steve Robertson

Hello Rick-

Thanks for the encouraging words. It's good to know that I am not the only one who has trouble with these things. I have a BS in EE, but find that I learned very little of practical value during my college education. That's one of the reasons why I got interested in Ham radio in the first place, actually.
I am now planning on getting my masters in EE as well, to hopefully fill in some of the gaps that I obviously have in my knowledge.
I find that analog electronics are just not being taught very much anymore. I learned plenty about digital electronics and have designed and implemented quite a few projects using micro-controllers, but until I really started building analog circuits, I didn't know anything about simple things like transistors beyond the mathematical equations that were drilled into us.

Thanks again for your post and congratulations on building your radios! Hopefully I'll be able to join you on the air with my own home-built equipment soon!
(I have the General class book sitting on my night-stand and am studying for that test.)

:)
Well, that confirms my suspicions!
Thanks for letting my down gently, though :)

> in Vmod to the emmitter of the rf transistor and bypass it with
> the RC-combination 0.1u/100 Ohms. That is not a good idea
> because the transistor can get direct current from the ground
> line and so bypasses the modulator transistor or whatever you

Yes, it's a NPN BJT (I use a model for a Q2N2222)

> have there. The waveform that I can see on the picture is not
> AM, it looks like some sort of incomplete superposition of two
> different sine waveforms.

OK. The reason that resistor with bypass cap is there is to stabilize
the quiescent current, and give the circuit a bit more gain at higher
frequencies.
I can get rid of that resistor, though, and try it again.
If I get around to it tonight, I'll post new pics on my site.

What's surprising to me is that the Spice output seems to show something
like AM modulation, right?

> To point it out again: If want to have a proper amplitude
> modulation you must lead the *complete* current of at least the
> final stage of your transmitter thru the modulating device. It
> is even more recommended to co-modulate also the stage in front
> of the final stage. But, you should not modulate the oscillator,
> this might lead to unwanted FM.

I guess I don't quite understand what you mean by that: what do you mean
by "lead the complete current [...] through the modulating device"?
Could you explain that more in detail, please?

> In our school library we've got some of the older books dealin'
> with AM radio control transmitters. Unfortunately ;-) this week

That'd be great, but I don't want you to go to more trouble than you already have. You've already spent so much time helping me, I don't even know where to begin thanking you.

I'll post any new results to my web-site at the same location as before. Thanks again for your help!

I am building an HF Amplifier and I am in need of Three , I am building an HF Amplifier and I am in need of Three 1/4" flexible shaft couplers for my capacitors and roller connections. These are the couplers that have a 1/4" collar on each side with a ceramic circle center to isolate the conductivity of the shaft.

I have searched the web and every hamfest that I have been to since January and have not found any as of yet. I would appreciate it very much if any one can help me.

Please reply to me direct. kb4i@comcast.net

Please state price and condition.

Thanks,

The initial round of PC boards is back and as usual Richard Hosking (and
his board house) have done a great job. Pics at:

http://209.95.122.40/jm/synth2.jpg
http://209.95.122.40/jm/synth.jpg

The synth is up and running fine on this PCB, and once we make a few
minor tweaks (like simplifying the DDS power supply regulator circuit
and substituting an improved part for the ERA-5 MMIC), the boards should
be ready for purchase via PayPal from Richard within a few weeks. Cost
should be in the neighborhood of $20-$25 per board, similar to his
AD9854-only boards.

When you operate a separate transmitter and transceiver, what steps do
you follow to ensure you're transmitting on the correct frequency?
Assuming no fancy or accurate frequency displays, I guess you have to
listen to your own signal, to zero-beat your own carrier as well as
the other guys. Or do you necessarily share an external VFO?

Totally unacceptable.
>Is loss of signal a MAJOR issue if only occasional.
Yes, can be critical, especially FM background hiss.
>Is performance or price the biggest issue - if you HAD to choose?
Performance.
>Is 433 @ 10mw the only acceptable solution?
Only modules I can find here. I would not even attempt to build
something like this.
>Are you adamant that the RX must also use a whip?
Will be housed in a small box together with a battery, loudspeaker,
and small amplifier. The antenna needs to be out of sight.
>
Hi Mark,
The idea is to place a louspeaker 100m from me. This is for calling
problem jackal, and to keep their attention away from me. The cd
player with me will be connected to the transmitter directly.There may
be some bushes in between, but I need line of sight for the rifle
anyway.
The antenna worries me. How can this be constructed simply, and be out
of sight?

Well, since you're just sending audio, why not just use FRS, or
whatever the local equivalent is? A couple of single channel units
would work fine at 100m LOS, and most already have audio input/output
jacks on them for connecting the CD player and a small amplified
speaker.

Ok John.

Several things come to mind here - the first being that 10mw @ 433 Mhz is
not likely to give you satisfatory performance.

The line of sight is encouraging and helps but if the RX aerial needs to be
out of sight, it also suggest it is not going to be of optimum length. that
said, notwithstanding the eyesight of the jackal - surely if the aerial was
painted brown / green it could be made to blend in reasonably couldn't it?

Wherabouts in the world are you John?

There are, for example a variety of "semi-powerful bugs" which typically operate around 75-120 Mhz - and although illegal to use in the UK, may be legal in your country..........

They will enable any FM radio to be used as your receiver (reducing costs) and will give a fairly good range (you can get a range of around 500M max which would give very good performance for your application) and the cost if usually around £20-£30. Most of them have a microphone built in but some also are avaailble with an AUX input.

One example, with 50mw output is available here http://www.veronica.co.uk/lpkit.htm and will cost you between £17 and £21 for a BUILT unit ready to run - price varies according to where it is being posted to.

Not legal for use in many Countries, but that is a matter for you to ponder, not me to judge.

At 50mW you are not likely to be causing a major nuisance to anyone - in fact it is incredibly unlikely anyone will even know you are using it providing you do not "sit on top" of the local radio station in which case neighbours may get a bit miffed.

Cheap, will do the job, ready assembled.

If you prefer to use the 433 system, I think you are going to need to either re-think the range you require and/or re-think your aerials a bit.

Mark

I hear where you're coming from, and even though the area is full of
potheads, this mentality is not at all prevalent. I worked there for five
years and *never* even one time had a client call my honesty into question..

And I hate to disagree with you, but in the twenty four years that i've
worked in this type of capacity in the San Francisco Bay Area and elsewhere,
I can't count the times on one hand that any coworkers have been accused of
stealing from a client..

> I hitchhiked the whole country in those days...I wouldn't dare hit a
> highway now. Things have indeed changed and thats a sad comment on our
> society. Its a great memory, tho.

The only time that I would pick up a hitchhiker would be if he was carrying
a gas can, and even then I would exercise extreme caution. If I use bad
judgement and get a knife or gun pulled on me, then we'll see how long it
takes him to hand it over or throw it out the window after I floor the gas
pedal and threaten to run into a concrete overpass abutment. If i'm gonna
die anyway i've got absolutely nothing to lose, but he does..

2603. More on 17m amp prob

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-05 08:12:30 UTC
From: n2cqr@clix.pt
Message-ID: <3cad5c53.4660852@news.clix.pt>
Source record: 45191

Thanks to all those who sent suggestions. I realized that I left out some needed info.

Here's the TX's lineup: Crystal carrier osc at 5173.5 khz. Balanced modulator consists of two diodes and nulling pot. Mic amp is an LM386. Four crystal (double lattice) filter from Swan 240. NE602 mixer with tuned circuit in output. LO is a VXO using a 12.954 Mhz rock. (I can only swing it 9 khz.) After the mixer there are two high Q tuned circuits (lightly coupled) as a bandpass filter. Then there is an MPF-102 amp (not tuned) (high impedance input to preserve the Q of the bandpass filter) then one fedback broadband 2N2222 amp. On the RF amp board there is one common base amp (because it was there and seemed to provide a good impedance match to the previous amp). Then a broadband 2n3866 and the two parallel Mrf 476s (also broadband).

The final stage was originally designed for class C operation, but I am biasing it for linear operation with the standard diode to ground through a 560 ohm resistor.

The biasing diode is NOT thermally coupled to the final's heat sink. Do you guys think that it would be worth the effort to move that diode so it would heat up along with the finals? What's the theory here? Would that make the diode conduct more, reducing the bias (and the gain) of the final as the thing heats up? Any tips on how to physically connect the diode to the heat sink (just a square of thin aluminum) How about Krazy Glue?

Even with this annoying problem the rig is working very well. 4X4UN said I was 20 over in Israel two nights ago. And everyone likes the audio.

The baby boomers aren't old enough for SS.
I come from the previous generation and just applied for SS and won't
receive it for some months yet. They had it the best of basically any
generation I've seen and they thought they had it the worst.

We have about another 8 years or so that they can still keep pumping money
into the stock market until the numbers drop significantly.

After them the next generation was the "X" generation, or lost generation, I
believe.
That was when we had the gas shortages (or was it still another generation
later...once you retire, you seem to lose track of time) we started to

recycle, move to cars that lasted and got good milage. Now we have huge SUVs and Trucks...actually they are selling more of those than cars and have been for at least three years.

The baby boomers were still in the time of "planned obsolescence". I had a Ford Mustang that actually rusted out by the time it was 6 months old. Pretty car...built like crap. The Ford company offered to stand behind it and pay half the cost of the repair...I could get it done for less than that at most autobody shops. Then the auto industry and unions couldn't understand why people started buying foreign.
>
I actually stayed with US cars until last fall when one of those imortal teenagers pulled out in front of my Transam with his invinciple SUV. I drove right through his door...The TAs wheels were big enough to put me over his frame. The only thing that saved his life was the massive door post on that GMC Jimmie. Shortened the TA up by about a foot and a half. Put the right front tire back into the firewall and there was no space left under the dash to get at the wiring because it drove the fire wall back so far. I wasn't even sore the next day. BTW, I only had time to leave about 12-15 feet of skid marks. I was punchy (and deaf) from the air bags for about half an hour.

The control head for the 2-meter rig was mounted on the dash. I stopped so quick, it layed down flat...Bent the metal right down to the plastic.

BTW, I had an FT101B and "thought" it had 6146s in it. Damn near got electrocuted off that rig due to a poor soldering job from the factory..

Interesting. I had a 1998 Mustang for over three years + 60k miles and didn't have a single problem with it. The best car I ever had. If my company didn't insist on giving me a company car, I never would have sold it...

Looks great - pretty as a Playboy bunny:)

Have you had a chance to look at crosstalk and spurs? If so, do you
see much difference between the pcb and the original?

Thanks for doing this, John. I can see a lot of simple, inexpensive
projects based on these boards. You are providing a new level of
performance and capability at a very inexpensive price, and I expect
to see your boards used in many ways.

For example, this would provide the perfect trigger for an
inexpensive, high-performance sampler I've been working on. You can
see the description at

http://www3.sympatico.ca/add.automation/sampler/intro.htm

Please let us know when the boards are ready!

Best Regards, Mike

Small Parts in Miami (web presence) used to have them- I used them in a 1296 cavity amp. 1/4" shaft one end 1/4" "socket at the other.
Even if the y no longer carry them, every homebrewer should have their catalog.

The antenna is no problem. A jackal has no idea what an antenna is.
If it makes you feel any better, you could paint it green. At
those frequencies, a 3-element yagi would fit in about a 1 sq. ft.
footprint (about 1/3 M square).

>the other guys.

Yep.

Hopefully, your transmitter has a "spotting" switch which causes the
low-power stages to generate a signal without feeding it to the power amp or
antenna. That way, enough of it leaks through for you to hear it and
zero-beat the other guy, but none of it gets radiated to interfere with the
people you're trying to zero-beat.

I measured it using Radiometer Q-meter with 500pF (max internal
capacitance), it was somewhat above 136kc, possibly 150kc, so I
assumed the difference wouldn't be too much on 136kc

Tonight tested a 4.4mH coil from similar SRT carrier frequency
equipment, and with 500pF - below 100kc the Q was very high, peaked
the scale with lowest setting of power, maybe 900, but cannot be
confirmed. With external 1.06nF (total = 1506pf) it resonnated on
60kc, but now Q measured only 500.

>To calculate the Q of the two coils in series, in addition to
>calculating the combined inductive reactance and resistance, you also
>have to calculate the resulting combined distributed capacitance and
>from that the capacitive reactance, combine the parallel connected
>inductive and capacitive reactance and calculate the Q by applying the
>series resistance (losses).
>
well, the question shouldn't have been asked the way I did, and I
cancelled it within seconds (forgot it was in the outbox), but just
too late. The smaller coil is loaded with antenna impedance and the
actual total Q is much lower, somewhere in region of 30-40 dependent
on antenna impedance, which may be 75 ohm - from the active antenna on
the roof (so it is no question of loop aerial).

It was a concept for 136kHz dual conversion converter to 3560kHz I'd
like to try, it is now finished, but I think I'd better try another
solution, because the first mixer may be overloaded, so selectivity in
first IF may not help. I am looking into using SL6440 device which I
was given today. But interesting to try the experiment and wasting
some time, hi.

It is an interesting article in ARRL handbook 1981, page 16-34....,
Operating Impedance Bridge, covering at least 160-6m, possibly 144MHz.
You could use some more modern detectors like LTC5507 or MC3356

LA6VM once built it and made a demonstration at the local club of this
instrument, believe the idea is patented and has been produced in
larger quantities for the navy

it was a french idea on such design, because you don't need a complete
screen, chicken fence will do, and it is possible to use larger holes
in the screen, believe the principle is called Ruse-antenna

The main problem is to find suitable low resistance wire to reduce
losses, since radiation resistance is in the region of micro-ohms

I may have made a drawing for l'antenna de la Rouse

Message-ID: <01c1dce8$f8ed28e0$59274f0c@oemcomputer>
Source record: 45060

I would like to understand how a transformer can change phase. I think a center tap can invert the phase. I guess this applies to current. I do not know if this can apply to voltage. I would like to understand if different phases can be created by using a tap at different places on a coil. I would like to understand if there are a lot of waves with different frequencies will all the waves have the same change of phase.

Thank you for any answers.

2619. Re: transformer inverts phase

it doesn't 'invert phase'

the input and output waveforms may be of the same polarity or of opposite polarity, depending on which end of the winding is being used as a reference, but to say it 'inverts phase' in not accurate (although commonly used).

Actually, since I am a Novice I have a very small band to operate in. So, much like the novices of a generation ago I am rock bound. Sort of. I actually have a couple of rocks in both the 80m novice band and the 40 meter novice band and I modified the original McCoy transmitter design with a variable cap and coil so I can pull the rocks about 3-5kc, which is not enough to get me out of the band but does give me a little latitude to play with. I also have a McCoy designed transmatch to make sure I'm not radiating strong harmonics.

But just to make sure I put my computer designer skills to work and built a frequency counter based on an ATmel AVR that is coupled to the oscillator output and monitors the frequency. I also built a bar LED decibel meter that measures the power output of my frequency and the next two harmonics at the antenna. A fudge and a cheat I know but I'm building a tube VFO based on another McCoy design (is there anything that man could not do?) and today's FCC requirements are a bit more restrictive as to band tolerance and harmonic radiation. So I felt it would be prudent to keep a close eye on my transmission. Like I say, not strictly in keeping with the old time tube

tradition but it should keep the feds and my fellow neighborhood hams happy.

Nice thing about being rock bound is that if I switch out the VXO device and go strictly by the rock frequency I can tune my HB receiver to that exact frequency. Thus I always have a known good starting point on my main HB receiver dial or any of the experimental regens that I'm always building (3 hollowstate including one with galena crystal/cat whisker detector and "30" amplifier tube, and 2 solid-state, so far).

The PCB's broadband noise floor seems to be a couple dB worse, but
in-band noise appears to be pretty much the same.
http://209.95.122.40/jm/compare.gif shows an early prototype (not the
same as the ADF4112-based unit on my web page) in purple, with the new
PCB in blue.

The open point-to-point layout of the prototype has less broadband noise
(presumably from the digital section), but it's picking up 15.7 kHz junk
from a TV in a neighboring apartment. The PCB has better self-shielding
properties but also worse intra-circuit coupling. Not unexpected.

Overall noise performance, both in-band and out-of-band, is still
superior in the ADF4112 synthesizer at
http://www.qsl.net/ke5fx/synth.html. But the loop on the PCB uses an
easier-to-obtain chip and locks up quite a bit faster.

True - the only way to change phase is by creating a time delay in one
of the signals.

> so it would heat up along with the finals? What's the theory here?

The forward voltage drop of a p-n junction decreases with an increase in temperature. That is what contributes to thermal runaway in a bipolar transistor. I'm not too sure that the statement that beta increases with temperature, but I have been wrong before.

> Would that make the diode conduct more, reducing the bias (and the
> gain) of the final as the thing heats up?

The drop across the diode (ie the bias voltage) tracks the drop across the transistor's p-n junction, thus providing enough bias to maintain the same base current with changes in temperature.

> Any tips on how to
> physically connect the diode to the heat sink (just a square of thin
> aluminum) How about Krazy Glue?

Mount the diode in physical contact with the heatsink and use some heat sink compound to thermally bond it to the sink. The stiffness of the diode's leads will probably be enough to hold it against the sink.

Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Just received the Fox-Tango Newletters library. I am interested in performing several of the mods listed, starting with the doubly balanced mixer in the receiver, using the MC1496. Although no circuit board patterns are disclosed in ANY of the volumes, I believe I have enough information from the schematics and parts layouts to construct the mixer unit. Does anyone have experience in fabricating their own mixer boards and could provide suggestions? How much difference does this mod make in the receiver, which seems poor on 10/15 meters at present? Several experimenters mention IMD problems due to the IC used. Any better substitutions?

Any other mod suggestions would be appreciated.

Thanks,
AB

John
Would shielding sections of the board and/or separating parts of the ground plane make any difference?
Also the close in phase noise of the ICOM LO was much worse but the noise at 10 KHz was much better than the point to point version. Was this due to loop filter design or could you identify some other reason - eg VCO performance etc?

> etc?

As I noted in my earlier reply (to Mike Monett?), the Icom's strength is its twin-discrete VCO design. They use a very low loop bandwidth, less than 100 Hz as far as I can tell, and much higher-quality VCOs that cover only half the range (770-1290 MHz as opposed to 1000-2000). There is no way to make an inexpensive off-the-shelf integrated VCO compete with theirs -- I'm doing well to get as close to their performance as I am.

It's possible that some type of shielding arrangement could buy another dB or so in the broadband noise arena, but I doubt it would be worth it.

>(1) Do you even think it's worth doing it? Can a low-power radio such as
>mine even power a home-built antenna? Has anybody here used this
>transceiver with a home-built antenna before?

I've used 5W and less HT's with my antenna, which is based on the ARRL
handbook's simple quarterwave. Click on the picture of it on my
website for details.

>(2) I am very worried about damaging the radio. Are there any checks I
>can perform before hooking up my home-built antenna to the transceiver?

Well, the guys who say your factory rubber duck is a dummy load are
only part right; normal dummy loads are much better. If your coax is
good and your radiator and all radials are somewhere in the
neighborhood of 19" long, you'll be close enough to avoid damage.

>(3) Currently I am planning on building an antenna I found in the ARRL
>Handbook: the "1/4 lambda antennas for home, car and portable use"
>project (basically a vertical with ground-radials mounted at its base).
>Has anybody ever built that one? How well did it work?

Quite well, considering I've been using it indoors most of the time.
It doesn't match a copper pipe j-pole outside for performance, but
it's much better than anything that mounts directly on the HT.

>(4) Do I need a balun for the antenna if fed with coax?

I've never bothered. SWR on mine is easily adjusted to 1:1, and
rarely goes over 1.3:1 on 2m unless I forget to put the top part of
the radiator on. :)

>(5) I also read the chapter about transmission lines and understand
>there is a problem with using long runs of coax for VHF frequencies. How
>long can I make my transmission line before a noticeable degradation
>occurs?

Depends on what you're using. If you're going more than 25-30ft, it
might be worth investing in a run of RG-8, especially if you plan to
use it for UHF in the future. (Note that the 2m antenna's SWR and
performance on 440 is pretty darn good.)

>(6) What would I use for my transmission line? All I currently have at
>home is RG59/U coax from television installations. Does coax like that
>work?

Well, it works for some things...I have three spools of it as
heavy-duty doorstops here, but I wouldn't really want to use it for a
long feedline when 50ohm coax is reasonably easy to get. Radio Shack
usually has RG-58, and sometimes RG-8.

>(7) What is the best place to buy the hardware from that I'll need for
>construction? The project in the Handbook calls for brass or steel rods.
>Does the Home Depot carry that kind of hardware? If not, I also know of
>an Ace Hardware store around here: would they carry it?

Probably; all my parts came from Lowe's, but in retrospect, I should
have used the smaller non-chain hardware store for most of it.
(Better selection of fasteners at better prices)

>(8) I am planning on sticking the antenna out in my back-yard somewhere.
>Does anything speak against using a simple PVC pipe to raise the antenna
>off the ground?

Not at all. Look at the details of my mast. You could simply cut the
bottom of the pipe at an angle to make a spike, and drive it into the
dirt, or make the base like mine and put cinderblocks on the legs for
more portability.

>(9) Does the antenna need to be connected to a ground rod? I guess I
>don't quite understand why some antennas do have to be and some don't.
>It seems that HF antennas need to be connected to a good ground system,
>whereas these don't.

If you get problems with the radio interfering with other stuff, you
should try grounding the antenna. OTOH, the copper j-pole is also
pretty easy to build, and you can just drive the leftover 3/4" pipe
into the ground to make a (short) mast that will also act as a ground
in the right soil.

Hi Mark,
I am wary of doing anything illegal in this venture. Already one
attracts attention from the law if you shine lights around at night,

even if it is the necessary red light. One also attracts interest from greenies and other misguided animal lovers, and I want to keep on doing this. I am not sure if these units will be illegal here, but I presume anything over a certain power in the 88-108Mhz will be illegal. On the other hand, it will be the least part that attracts attention, and it would be difficult for them to prove it is illegal. The light, and the rifle attracts attention, and I will ensure that I stay within the hunting ordinaces.
I am in South Africa, and with the change in government, this was made more difficult, as there are now so many provinces, each with different ordinances. Also each province costs you another hunting licence.
No, the range cannot be reconsidered, jackal are very sharp, and they tend to circle downwind first. You need to get his attention further from you. 100M is a compromise already, and you still need to shoot if he is at least 50m from the loudspeaker. 150M is as far as I would like to shoot at night at such a small moving target. It is not easy, and morally one tries for a clean kill.
The advantage of what you are suggesting is that one can use a cheap car raido as receiver. That will give ample sound output, and already works off a 12 volt battery. Package the radio and the battery in a box (with a small red reflector so you don't kill it) and you are done.
If I recall correctly, there is an avaition band above the 88-108Mhz band, with a decent interval between, so if I can be at 110-115Mhz, I should be in the clear. The car radio could be retuned to cover that. That would still be illegal, I presume, but out there in the bundu, who cares?
Thank you,
Regards
Johan Smit

???? Shouldnt a well designed PCB have better intra-circuit coupling? The
flying wires of the prototype should pick up much more (digital) noise than
the (hopefully) well layouted PCB. Did you measure both version inside a
metal box (shielding)?.

yes, it was some silly notes about improving FT-101 using MC1496P and
this was the reason for buying FT101B, but it later turned out that
MC1496P has an IP3 of -20dBm which would not be an improvement at all

Have borrowed several FT-Newsletters from DK3UZ to look at possible
improvements for FT-7 and FT-902, but didn't find anything useful,
most of the mods were more based on feeling than based on practical
experience

> >transceiver with a home-built antenna before?

The lower the power, the more important it is to have a good antenna. Don't
feel like your HT doesn't have enough power for the antenna. Instead, think
of the product of the antenna gain and the power. Big antenna + low power
is roughly equivalent to little antenna + big power.

> >(2) I am very worried about damaging the radio. Are there any checks I
> >can perform before hooking up my home-built antenna to the transceiver?

Your HT probably has SWR protection. Even if it doesn't, the main thing to
avoid is open circuits and shorts. Be a little careful and you will be OK.

> Quite well, considering I've been using it indoors most of the time.
> It doesn't match a copper pipe j-pole outside for performance, but
> it's much better than anything that mounts directly on the HT.

Since you are thinking of mounting it outdoors anyway, a J-pole may be a
better choice. You get more gain, and a little simpler construction.

> >(4) Do I need a balun for the antenna if fed with coax?
>
> I've never bothered. SWR on mine is easily adjusted to 1:1, and
> rarely goes over 1.3:1 on 2m unless I forget to put the top part of
> the radiator on. :)

There are baluns and there are transformers. Baluns don't have anything to
do with SWR. If you have an unbalanced feedline (coax) and an unbalanced
antenna (1/4 wave) then a balun is irrelevant. With an antenna impedance
reasonably close to 50 ohms (OK, a vertical isn't exactly 50 but it's close
enough for engineering purposes) then a transformer will introduce more loss
than it saves.

> Depends on what you're using. If you're going more than 25-30ft, it
> might be worth investing in a run of RG-8, especially if you plan to
> use it for UHF in the future. (Note that the 2m antenna's SWR and
> performance on 440 is pretty darn good.)

Go look up the loss for the feedlines you can find/afford. Since you are comparing to a rubber ducky, which is probably somewhat poorer than an isotropic radiator, it's a little hard to tell what you will gain in the antenna over what you have now. But it's easy to loose 6 dB or so getting to the antenna at 2 meters. At 440 the problem is a lot more severe. 100 feet of RG-58 is a pretty good dummy load at 440, and better sheilded than most, too!

> Probably; all my parts came from Lowe's, but in retrospect, I should

I like Lowe's for antenna parts because they have a big selection, but they may not be the cheapest game in town. Sometimes at the corner hardware you will find someone who will listen to your problem and be pretty creative about helping you find things you can use. In my experience, if you're not doing the expected like putting in kitchen cabinets, you will get a blank stare at Lowe's.

> >(9) Does the antenna need to be connected to a ground rod? I guess I
> >don't quite understand why some antennas do have to be and some don't.
> >It seems that HF antennas need to be connected to a good ground system,
> >whereas these don't.

Even if you are low enough that a direct lightning strike is unlikely, at times of high electrical activity a tall, pointy thing will tend to draw static which could damage your radio. I like to put a high resistance (say 1 Meg) between the non-grounded part of the antenna and ground to safely drain the static without affecting the RF performance. If the static can't build up, you tend not to draw direct strikes. However, if you do take a direct strike, the only thing that will save your radio is having it disconnected. A lightning arrestor between the antenna and ground won't do much for your radio, but it will prevent a strike from following your feedline and setting your house on fire. If the antenna design is one that can be entirely at DC ground then both of these needs can be handled by simply grounding the thing.

> If you get problems with the radio interfering with other stuff, you
> should try grounding the antenna. OTOH, the copper j-pole is also
> pretty easy to build, and you can just drive the leftover 3/4" pipe
> into the ground to make a (short) mast that will also act as a ground
> in the right soil.

A word about interference ... the bigger and taller your antenna is, the LESS likely you are to interfere with other equipment. If you don't have a problem with the rubber ducky, you won't have a problem with the outside 1/4 wave. It will be farther away from the equipment you might interfere with, and if it is higher than the TV sets, it will prefer to radiate out horizontally, away from the TV's, phones, stereos, etc. The problem with a tall antenna is that it attracts the neighbor's attention, and suddenly every little ailment becomes your fault.

That will put you right in the aviation navigation band (108-118) and
aircraft within as much as 250 miles could suffer interference. I think
you could find yourself in a heap of trouble operating there!

You could always use a cheap set of wireless headphones - they operate on 864Mhz (aerials are small up their), you get a transmitter and headphones for around ï¿½30 here in the UK and will do 100 meters without adding any external aerials.

They are fm stereo so the sound quality is well good enough, take very little power too, all you'd need to add is a small audio amplifier (maybe) and a loud speaker to replace the headphone speakers.

Clive

2654. Synthesizer Spur Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-06 16:29:26 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <o67uau0ql3fs649b1m8d58dbj0ohaiaelg@4ax.com>
Source record: 45096

I've been working on a 500 KHz - 2 MHz, 1 KHz step synthesizer. I'm using a 74HC4046 VCO/Phase Detector. Reference frequency is 1 KHz, obtained from a 74HC4060 running with a 8192 KHz crystal and I'm using a 4059 parallel load divider, presently hard-wired for divide by 800 for experimentation. I'm using the Type II phase detector output of the '4046. Kvco is about 500 KHz/volt.

My loop filter looks like this:

```
[13] --- 100K --- + ------+--- [9]
| |
1.0uF = = 0.2uF
| |
\ Gnd
/
\ 10K
/
Gnd
```

[13] is pin 13 of the '4046, phase detector output
[9] is pin 9 of the '4046, vco frequency input

Here's the problem and the associated question:

The loop locks up and sounds reasonably good on a receiver when listened to in USB or CW mode. However, the 1 KHz reference spurs are only about 60 dB down from the carrier (measured 25 KHz from the carrier) and they go out forever (to well over 100 MHz). My spectrum analyzer has a minimum resolution of 1 KHz, so I can't measure much closer than +/- 10 KHz or so to the carrier at a -60 dB level. Construction technique is Manhattan-style, so it has a decent ground reference. Vcc is decoupled with 0.1uF caps and ferrite beads for each IC.

The questions are: With the relatively simple RC loop filter, should I see better reference spurious supression, or is 60 dBc as much as I should expect? Or, is the limiting factor the 4046? Or, should I go back to more work on the RC filter? (I've already improved the 1 KHz rejection from an initial 35 dB by "fine tuning" the loop filter from my initial values.) Should I be looking at an active integrator with an op amp? This is the first synthesizer I've built, so I'm traveling down a new road.

By the way, the ultimate idea here is a 100 mW AM broadcast band transmitter, so that I can pipe various audio signals around the house via AM BC receivers. -60 dBc spurs are (barely) acceptable for this

purpose, but I'd rather have it look cleaner.

No, both of these graphs were taken with the board sitting on the
bench. I should clarify: the cleaner "prototype" version had no digital
circuitry at all associated with it (except for the counters and latches
on the PLL chip itself). Its reference was either a fairly-clean
external signal generator (HP8662a). By comparison, the PCB has the
deck stacked against it because all of the circuitry including the DDS
reference is on one small board.

G,

What makes you think that I am not listening or checking out all the sources each has mentioned? I have diligently searched and checked all sources and may have found some items that will work.

I do enjoy reading the news group, but I don't think I need to be bashed by someone who thinks they know what every person is doing on the net.

Also, I do appreciate all the help from the group and hope you all have good rest of the day.

Thanks.

Phillip Johnson KB4I

The thing that concerns me is that you don't know how strong the spurs are at a 1 kHz offset. Reference spur levels are usually quoted at an offset equal to the reference frequency itself. If you have a rig with a narrow CW filter, you can use it to get an idea of how bad things are close to the carrier.

Also, I don't understand why they're extending to 100 MHz... are you using a good RF-grade capacitor for C2?

One problem is that your reference frequency is relatively low. A simple RC loop filter can't be expected to attenuate it very effectively, unless you drop your loop bandwidth even farther. If you can move to a 10 kHz reference, things should get a lot better. No need for 1 kHz tuning steps on the broadcast band, right?

Another option is to construct a notch filter specifically tuned to 1 kHz and hope it doesn't destabilize your loop by introducing too much additional phase shift at frequencies where your loop gain is still >1. I'm a little concerned that your loop is already unstable, though, because you should not be seeing anything at 100X the carrier frequency.

> The questions are: With the relatively simple RC loop filter, should I
> see better reference spurious supression, or is 60 dBc as much as I
> should expect?

-60 dBc is reasonable reference rejection for most purposes (as an example, the purple graph at http://www.qsl.net/ke5fx/synth/medium.gif shows -65 dBc reference spurs in an Icom rig with a 5 kHz reference frequency), but the key is, there should really only be one set of reference spurs at offset=+/- Fref. A whole forest of spurs usually means oscillation.

You might check out http://www.national.com/appinfo/wireless/ -- they have a nifty web-based PLL design program based on Dean Banerjee's work. It's geared to their PLLatinum chip line but can be used if you know your 4046's analogous specs. You can run a Bode plot to check your stability. That 0.2 uF cap across your VCO might be a bit much, for instance.

> Or, is the limiting factor the 4046? Or, should I go
> back to more work on the RC filter? (I've already improved the 1 KHz
> rejection from an initial 35 dB by "fine tuning" the loop filter from
> my initial values.) Should I be looking at an active integrator with
> an op amp? This is the first synthesizer I've built, so I'm traveling
> down a new road.

The 4046 is fine for this purpose, and you should use an active filter only when you need voltage gain -- for instance, if your VCO needs 1-20V to tune it but your PFD charge pump only puts out 0-5V. You're already driving a load (the VCO) with a very high impedance at the filter's operating frequency, so all an op-amp is likely to do is give you more noise.

> By the way, the ultimate idea here is a 100 mW AM broadcast band
> transmitter, so that I can pipe various audio signals around the house
> via AM BC receivers. -60 dBc spurs are (barely) acceptable for this
> purpose, but I'd rather have it look cleaner.

Right, -60 dBc is fine at a 1 kHz offset, but not at 25X the reference frequency. Your first step should be to move to a 10 kHz reference, where your analyzer can give you a clear picture of what's really happening.

Yes, I think I agree here. In fact, upon re-reviewing the Newsletters, someone mentioned that the original MOSFET's were actually better than the 1496 in most cases. Good point! However, not to sound like I'm contradicting myself, I have an unused 1496 sitting here along with parts boxes with all the parts needed to construct the mixer. I think I'll try it anyhow and see what happens. The receive is weak on the higher bands, especially 10 meters, and the bleed from close stations is terrible. I need to try something.

I'm not sure what opinion I have of the Newsletters at this point. Seems like a lot of experiments were tried and failed but others were successful. And at least some of the content does seem theoretical rather than "practical".

2663. Re: Synthesizer Spur Question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-06 22:09:39 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <14ruau8hnvoj0k3i4u6jpm03caskb480s2@4ax.com>
Source record: 45004

John:

Good suggestions. Here's what I've found:

(1)You will find a couple of scope shots accompanying the following discussion at http://home.cox.rr.com/k8zoa/Synthesizer.htm

(2) I moved the reference tap to 8 KHz, and rewired the jam inputs to the 4059 to divide by 100, thereby returning to the 800 KHz test frequency. (I didn't have a crystal that yielded 10 KHz with the 4059.)

This changed the loop filter parameters, so I resorted to the old "replace the fixed R's with pots and adjust until the results look better." The R values are a lot different, series R was 100 K, now 2.3K, damping R was 10K, now 250 ohms.

By adjusting the two resistors, I was able to get the phase detector output "kicks" to have a clean damped response without ringing. (If I squint a bit, though, there looks to be a periodic signal buried in the noise. I don't trust the "1.96 KHz" C1 auto measurement.)

(3) The results look a LOT better than with the 1 KHz reference frequency. Still not quite where it should be, but it looks more like a synthesizer than a broadband quasi random noise generator.

(4) I thought about 10 KHz steps but decided that it would be much more flexible with 1 KHz steps. But, the results are so much more promising with 8 KHz steps that I will give up on the 1 KHz idea.

(5) As you can see from the scope shot, I'm seeing quite a bit of noise on the VCO steering line. I'm not sure if this is normal or something of concern.

(6) As you can see, I can now resolve the first sidebands and they are 44 dB below the carrier.

(7) Also, the wider span shot shows the higher order spurs do roll off (albeit slowly), unlike what I was seeing with a 1 KHz reference.

(8) I did see the National App Note and built an Excel spreadsheet a couple days ago to implement the calculations. When I tried to implement the resultant design, I found that any capacitance at the output of the phase detector (even as little as 33 pF) caused severe loop oscillation. I also found the simplified technique in the Fujitsu app note of some help as well.

I have all of the required constants (Kvco = 415 KHz/volt, based on measurements and curve fitting) except the charge pump output on the 74HC4046. In terms of voltage, it swings Vcc for 4xpi radians. I believe that translates to around 5 mA for 4 PI radians, based on the short circuit output current of a logic gate in the 74HC4046, but I'm not 100% comfortable with that conversion.

IIRC, the European version is called PMR446 or soemthing similar.
Basically, it's the cheap UHF walkie talkies designed for families to
keep in touch over short (about a mile in most outdoor conditions)
distances. The American FRSs work on 14 channels in the 462-467MHz
range, and cost between US $15 (For single channel toys) and $70
(Fancier ones with FM broadcast receive, weather alert, and whatever
else could fit into the case) I have no idea what the price range or
specification for the European version is.

> voltages?

Yes - High power means high voltages in the RF circuits. You will see large air spaced capacitors in high power tuners for this reason.

Transmitters use impedance matching to match the relatively low impedance of the transistor output to the higher antenna impedance. Impedance matching changes the currents and voltages at the input and output to match what is driving it (the final transistor/valve in the transmitter) to what is being driven (the antenna) without loss of power.

For wideband HF amplifiers this impedance matching is can be done using wound transformers as you suggest. Other methods are also used such as tuned coupling (eg PI coupling) or stipline impedance changes at higher frequencies. Take a look in the plate / collector circuit in RF power amplifiers in the ARRL handbook you have.

The power supply needs to supply only the correct voltage to drive the transistor/valve you are using.

I've used douzens for MC1496P and MC1596P for several projects, also
S042P, but it is better devices around. Just got some SL6440, and they
have high IP3, so I don't understand a reason for using a bad device

In fact I don't see any point to waste time on FT-101/B or FT-221 or
FT-225 which are all made to same principles and suffers from bad
carrier oscillator leakage which upset AGC,. So without any chance of
good audio quality it is no point to waste the time,....but somebody
had a point: "It is a good transmitter". I usually prefer to hear what
the opposite stations says, but it is different opinions about that

I spent a week trying to find the reason for the problem with FT-101B,
but never succeeded, later tried it with FT-221, and withing a week I
managed to make only very inferior improvements. Although I had very
sensitive RF voltmeter available I couldn't trace what really caused
this radiation of carrier signal from the oscillator to an early stage
of IF, og possibly RF mixer. You can remove the carrier connection to
the product detector and still receive ssb signals as normal.

Unless VOR et al has become suddenly a bit more sensitive of late, I would be a little surprised if 50mW would cause interference 250 miles away. Shag, one transmitter the size of a pack of fags could take out the entire UK nav system (and France / Ireland for good measure). I have enough drama getting the local beacon at Daventry when I'm more than a a few dozen miles away - and that's with a pretty good line of sight and with Daventry putting out a bit more than a twentieth of a watt, It's also with equipment designed for the job.

That said, I would tend to agree that transmitting on Aircraft freq's is a pretty silly move.

In the dim and distant past, I always worked on the basis that 100 Mhz on the nail was a good one to transmit on if you WERE going to transmit illegally. So many devices emit RF at 100 Mhz unintentionally that I have never heard of ANYTHING critical being used on that frequency. Certainly I would not anticipate national calamities occuring with 50mW on said frequency.

The little transmitters from Veronica are actually quite "clean" as far as it goes, in fact they also make "proper" transmitters which are acceptable for use in the UK with licenced operators. Even the "toy" ones are quite well designed.

I would say the nearest neighboiur is more likely to get uptight about rifle shots in the night than anything else. :)

Mark

Hello Everyone-

I'd like to thank every one of you who took the time to reply to my inquiry. I greatly appreciate all of your help and input.
I went to a couple of stores today to get the necessary hardware and built my first antenna: I decided to go with the 1/4 lambda ground-plane verticle listed in the ARRL Handbook and mounted it on a PVC pipe in my backyard.
The signal reports I have gotten so far were all outstanding. I am also able to make a repeater that I could never get into before, so it seems like everything is working out great.

Thanks again to everyone for your input & support!

Congratulations! - great to hear it's working.

Take a shot at 146.52 simplex. (whether it does any good is very dependant
on local activity..) That'll *really* prove the antenna...

I am in need of information for a part on my Texscan AL-51 Spectrum Analyzer. The 1 to 2 ghz oscillator is dead and I traced the problem to a stack of four tuning (vericap) diodes with a part number of MDT606. I have not been able to locate the part number or a cross reference to this part. Might anyone out there have information on the defective part; or perhaps an extra part (or even the oscillator module itself)? Gladly pay reasonable costs. Please respond to my email address. Thanks and 73's Don Smith KB6GQA

Cleaning up the shop and here's a pile of junk that's collecting dust.
Email me with any questions or if you need a pic. I may trade all or
part for a decent HF general coverage receiver. Whatever the offer,
any personal checks must clear before I ship.

==========

* Jackson 640 signal generator, connectors replaced with BNC's;
* Heathkit IG-72 audio signal generator;
* Hickok model 121 (cardmatic) tube tester, includes cards for 322
tubes, approx 50 lbs;
* O-scope, Telequipment model S54A (doesn't work, no power); 20 lbs;
* Power transformer, Marantz. 8VAC, 68.5VAC, 73VAC (low current),
should easily power a 300W audio amp; 17 lbs;
* Power transformer from ARC PS; 117VAC 7 step primary; secondaries:
315 - 415VAC; 66.0 - 86.4VAC/CT; with matching chokes, and with cap
for LV winding; total weight 15 lbs;
* Transformer: Originally a power splitter/isolation transformer,
230VAC @ 15A max input, two 115VAC outputs. Secondaries removed
(they were cooked). Primary on bobbin is estimated 248 turns of
BWG#11, and ready to wind a new secondary to your specs. Core
consists of four laminated U-cores that could easily be gapped.
Whole thing is easy to assemble and mounts in a steel box, approx
10" cube, w/carrying handle; total weight approx 40 lbs.
* DY-9/ARC-1 Dynamotor, 8 lbs.
Input 26VDC @ 4.0A, output 360 VDC @ .135A continuous,
Input 26VDC @ 7.5A, output 310 VDC @ .355A intermittant;
* Carter DuoVolt Genemotor, Code No 6427VBNS, 13 lbs.
Input 6/12 VDC @ 51/25.5A,
Output 640 VDC @ .275A,
Intermittant duty, originally powered 6146 pair;
* One 15# spool of #26 enameled wire (bobbin adds 5 lbs to spool);
* One 1000' spool of Belden 9311 (RG-58A/U);
* JVC model 3050, AM/FM/PB, 3" B/W TV, w/AC adapter, only defect is
the antenna tip broken off;

==========

The following is a bunch of parts that were mostly scrounged from dead
radios. Some are real antiques. The parts will be sold as a lot. A
small goldmine for the homebrewer:

* Several dozen pots, rotory and slide types;
* A couple dozen tube sockets, octal & min, a few ceramics;
* 31 large crystal sockets, 19 ceramic;

* Small box of vari-caps, up to 400pF, air & mica, many trimmers;
* Large homemade dual vari-cap (seperate shafts, and pretty well made), 400pF each section, 1/8" plate spacing;
* A few small audio & power transformers, most specs unknown;
* A small box of selenium rectifiers, specs unknown;
* One dozen meters, a couple larger ones too;
* A bootboxful of various coils, switches, knobs, assemblies, etc;
* Hundreds of tubes, all pulls. Several shoe-boxes full of miniatures, some compactrons, and here's a list of everything else that I'm willing to part with:

1A7 1Q5 1N5x2 6A7 6AC7x2 6BG6 6BQ6GA/6CU6
6D6 6F6-G 6H6 6Q7-G 6SA7-GT 6SK7 6SL7-GT
6SN7-GTA 6SQ7-GTx2 6V6-GTx5 6146x4 6146B 12DQ6
12JB6A 12SL7-GT 41 80 7984x2 4X150Ax2

End of parts lot. I have other parts in the shop if you can think of anything specific that I can add to the lot, like chips, connectors, crystals, etc. I will not add any RF power transistors or any more tubes, so don't ask!

Do you have the URL so I can take a peek?

> I have the schematic, all of the parts listed, but how do I transcribe the
> schematic to the board? Where do I even begin?

I usually start out with a pencil and paper, drawing the aproximate
size of the parts, and follow the diagram for layout hints, most are
drawn as you would build the circuit. Graph paper is handy for a neat
layout.

Humans are much better than auto-routers, but there is software out
there that will do this automagically for you, and they scale a hell of
a lot better.

Most HAM projects are small enough to do by hand, if the circuit is
simple enough you can just build it dead-bug or manhattan style, the
stray C is probably still OK at the mid VHF of 2m, otherwise you can try
perf board with no copper and solder in pieces of copper or tin as
required for large grounding areas.

On the loop bandwidth issue, it is my understanding that the PLL will
attenuate VCO phase noise within the loop filter bandwidth. If the ICOM has
a very low loop cutoff, that might explain why the close in phase noise is
worse than our synthesizer. On the other hand phase noise on ours is worse
at 10 KHz - this presumably reflects the VCO fundamental phase noise
performance. Would it be worth setting our loop filter cutoff to as high a
frequency as possible, consistent with adequate attenuation of the reference
sidebands? In our case the reference freq is about 1.7 MHz. With a loop
cutoff of Fref/50 (this is a reasonable assumption for a quasi 2nd order
loop), this would allow a cutoff of 25-30 KHz or so.Phase noise would be
attenuated within this bandwidth by the loop filter.(I think)
On a related issue, is it worth considering a discrete loop amplifier,
rather than opamp? It is certainly possible to get lower noise with
discrete components while retaining the higher VCO control voltage swing

See if that project has templates to make a printed circuit board.
Many do I think. If not, you will have to design your own board
layout, or use wire wrap, etc. If they do have a template, you can buy
kits to make boards, or you could have it made. Simple boards are easy
to make. They sell marker pens to draw the traces out, but I don't
like those too much. They always seem to leak through a bit and have
trace gaps, etc. I like to use thin strips of tape to draw the traces
on a simple board as it has less problems with trace breaks. MK

Hi All,

Technial Topics in Radcom (RSGB) covered the problems of FT101 and strong signals and also offered a solution that I carried out and found to be very effective on my FT101B.

Details are August 1979 P739 & October 1979 P938.

Further details on request.

Source record: 45021

I know i am going to stir up some trouble. Please forgive me, i would not start it if i didn't need it.
I have a crazy neighbour that plays very loud TV during night time, all night.
Since she is crazy the Police cannot do anything.
I am looking for a short range (50 meters are enough) noise generator that could erase her annoying noises (white noise is quite more acceptable).
I tried to use a couple W at 430 MHz close to her TV antenna but, with my greatest surprise, nowadays TV are quite selective and this did not do the trick.
Can anyone help me? Technically it looks to me like a big challenge, since the spectrum is so wide.

Thanks

Some years ago xtal testers seem to be interesting projects, and several circuits were described in the magazines for handy tester you could bring with you when you were looking for surplus xtals, probably FT243 then.

Below is shown a simplified circuit for an xtal tester, this is just connected to my counter, and some xtals has been tested since the tuning capacitor is 150pF and will give some indication of xtal tuning ranges.
It seems that xtals made for colour burst oscillators may be pulled more than others, but otherwise xtals are pullable by a degree which rises with frequency, and channel xtals for VHF sets seem not less pullable than other xtals. The circuit is just an ordinary XO, not VCXO, but still xtals may have the required pull range for certain applications.

Well I'm not inclined to do the math on a Sunday morning but more than one person using aviation bands for things like garge door openers has run afoul of the law in North America in the past. And, I understand that in at least one major city not too far from me there have been serious interference complaints due to those little remote car starer/lock controllers to the extent that some repeaters have actually changed frequencies to get away from them.

Do you need to have 1 KHz resolution? I thought the AM band spacing was 9 KHz. It will mean that your loop filter cutoff will have to be around 20 Hz to get acceptable reference suppression. I dont quite follow your loop filter - it looks as though there is R (100K) in series with the VCO control line with a damped C to ground (usual). However there is an additional C to ground without an R in series to make the filter 3rd order I presume. Trial and error is difficult with PLLs - whenever I have tried it I have ended up with oscillation. Better to model them and plug some values to a softrware program.

Henry;

By your use of '180 degrees difference in phase' you've used a common
incorrect description of what is actually going on.

You mean (I assume, since you qualified it with 'is not a delay') that
'opposite polarity appears to be a 180-degree phase delay'; this is true,
but only for a symetrical wave-form.

Take as an example a wave composed of the positive-going half of a sine wave
followed by the negative-going half of a sawtooth wave.

If you invert it (opposite polarity) we get a negative-going half-sine-wave
followed by a positive-going half-sawtooth

On the other hand, if we delay it 180 degrees, we get a negative-going
half-sawtooth followed by a positive-going half-sine wave.

This is one of those errors in terminology that have been perpetuated by
textbooks. instructors, and common usage which call it '180 degrees out of
phase' (incorrect, but indistinguishable for a symetrical waveform), when
they should have said 'of opposite polarity' (correct under any
circumstances).

Not criticizing, just trying to ascertain what your true meaning was, and
give an example to illustrate the difference.

Regards,

G

Repost (found some more info):

Some years ago xtal testers seem to be interesting projects, and several circuits were described in the magazines for handy tester you could bring with you when you were looking for surplus xtals, probably FT243 then.

Below is shown a simplified circuit for an xtal tester, this is just connected to my counter, and some xtals has been tested since the tuning capacitor is 150pF and will give some indication of xtal tuning ranges.
It seems that xtals made for colour burst oscillators may be pulled more than others, but otherwise xtals are pullable by a degree which rises with frequency, and channel xtals for VHF sets seem not less pullable than other xtals. The circuit is just an ordinary XO, not VCXO, but still xtals may have the required pull range for certain applications.

Has anyone got any information on a radio, Marconi RC 748. It appears to be a repeater unit (VHF), in a 19" rack mountable case. Any info at all greatly appreciated, especially programming and tune-up instructions.

Thanks

Alec Wood M1BNK

Actually, a 180 degree phase shift is not the same as polarity inversion even for a repeating symetrical wave-form like 60 hz power. It only looks the same on a scope because you can't tell one cycle from the next because they all look the same. If you make any type of amplitude change to distinquish one cycle from the next, you quickly see that there is a major difference between polarity inversion and phase shift. Polarity inversion turns the waveform upside down without changing the time while a phase shift leaves the polarity in tact and shifts the time.

I wouldn't be worried so much with mixer conversion losses on HF, a good diode ring mixer followed by a properly designed low-noise IF preamp will do wonders. The trick is to use transformer feedback from the emitter lead vs. resistive feedback to set the impedances and gain.

Gain is a cheap commodity. Dynamic range isn't.

Pete

Richard Hosking wrote:
>
> On the loop bandwidth issue, it is my understanding that the PLL will
> attenuate VCO phase noise within the loop filter bandwidth.

Only in parts of the spectrum close to the carrier, where the PLL's own noise performance is better than that of the VCO. This, rather than reference suppression, is the real reason why narrow loops are more common than wide ones.

The digitally-derived reference's broadband noise floor (neglecting the effect of the crystal filter and comparator) is around -140 to -150 dBc/Hz. The PLL chip's dividers effectively multiply the reference noise within the loop bandwidth by 20*log(N) dB, or about 60 dB at 1 GHz with Fcomp=1 MHz. So the best a DDS/PLL synthesizer with N=1000 can do is theoretically -80 to -90 dBc/Hz.

It's true that the crystal filter should ease this limitation significantly at offsets beyond its own bandwidth. Unfortunately, though, that's not the whole story. As Dean Banerjee points out in his book, the phase detector chip itself also has an effect, in some cases more than the often-quoted 20*log(N) degradation. He states that a digital 3-state PFD causes a 10*log(Fcomp) degradation in phase noise relative to the chip's own normalized noise floor. Not many PLL data sheets spell this out.

In the LMX2326's case, Dean says that the noise floor normalized to a 1 Hz bandwidth is -210 dBc/Hz. So the predicted minimum phase noise within the loop bandwidth is given by -210 + 10*log(Fcomp=1 MHz) + 20*log(N=1000), or around -90 dBc/Hz. Note that for the loop conditions stated, this is an absolute best-case figure -- it can't be improved by tweaking the loop filter, cleaning up the reference, or praying to Claude Shannon for divine intercession! In practice, there are numerous other factors that contribute to close-in phase noise, all of which tend to make it worse (resistor noise and so forth).

Now, to answer your question, go back and look at the figures for the ROS-2150VW VCO part. If the loop can never do better than -90 dBc/Hz within its bandwidth, then it makes sense to choose a loop bandwidth in the neighborhood of the frequency offset where the VCO's noise performance passes through -90 dBc/Hz. This would be around 5-7 kHz depending on the shape of the noise curve between the 1 kHz and 10 kHz points specified by the data sheet.

If Dean's not smoking crack, then using a wider loop bandwidth than this should actually make the VCO *noisier* beyond that bandwidth, not cleaner. We can run an experiment on the board to confirm this, using otherwise-identical loop filters designed for 5 kHz (blue) and 30 kHz (purple) bandwidths.

At offsets significantly narrower than either loop filter's bandwidth, the performance is very similar:

http://www.qsl.net/ke5fx/misc/5vs30200.gif

But at carrier offsets beyond 5 kHz, the narrower (5 kHz) loop filter starts to "win":

http://www.qsl.net/ke5fx/misc/5vs302k.gif

The 10 kHz/division plot shows significant degradation at large offsets:

http://www.qsl.net/ke5fx/misc/5vs3010k.gif

At 10 kHz, the loop with the 30 kHz filter is 8 dB noisier than the loop with the 5 kHz filter. This would impair adjacent-channel selectivity in a receiver, although the 30 kHz loop certainly locks faster (only a couple of milliseconds to go anywhere between 1 and 2 GHz).

> If the ICOM has
> a very low loop cutoff, that might explain why the close
> in phase noise is worse than our synthesizer.

Right. A wider loop bandwidth would just bring the same degradation visible in the narrow R-7000 plots out to wider offsets, which is clearly not a good idea. In both Icom's case and ours, composite noise at 10 kHz is limited primarily by the VCO.... unless we use a filter that's too wide, at which point the PLL itself becomes the limiting factor

> On the other hand phase noise on ours is worse
> at 10 KHz - this presumably reflects the VCO fundamental phase noise

> loop), this would allow a cutoff of 25-30 KHz or so.Phase noise would be
> attenuated within this bandwidth by the loop filter.(I think)

This was my reasoning when I first started playing with PLLs a couple of years ago. It seemed to me that a DDS-driven PLL should be able to achieve lock times in the submillisecond range *and* provide exceptional signal purity, even with a cheap VCO. Now I understand why that was naive, although it's taken long hours of experimentation and study to become comfortable with the facts of life. There is just no getting around the fact that you need a clean VCO if you want a clean synthesizer.

If more manufacturers talked about that 10*log(Fcomp) term in their data sheets, I would have wised up a lot sooner.

> On a related issue, is it worth considering a discrete loop amplifier,
> rather than opamp? It is certainly possible to get lower noise with
> discrete components while retaining the higher VCO control voltage
> swing

Possibly a couple dB could be gained with discrete transistors, but the loop filter would become harder to tweak. I made a couple of half-hearted stabs at using the Icom R7000's discrete charge pump circuit at one point, but could never get the thing to settle down and fly right at the wider loop bandwidths I was using.

I don't think it would be worthwhile to mess around with other types of gain blocks. The OP-27 is a pretty quiet opamp -- it's good enough for the YIG driver section in the Tektronix 490-series analyzers -- and the R209/C216 combination seems to do a good job suppressing the broadband noise it does contribute.

Well, it doesn't look like the loop's oscillating, but it doesn't look normal by any stretch of the imagination. I still suspect instability. Not crazy about the fuzziness of the trace near the base of the main peak... that's usually oscillation.

Those sound much more reasonable. I wonder if your loop filter is picking up clock harmonics by capacitive/inductive coupling? Looks like those spikes are occuring at roughly 12-14 kHz intervals, rather than 8 kHz.

Why are you having to make this measurement at 20 mV/division? Can you record the result of a frequency excursion that represents a couple volts' change in the VCO tuning voltage, to get the noise out of the picture?

Noise on the VCO tuning line is ALWAYS of great concern. It should look
clean as a whistle, as far as you can tell on a scope.

Ulrich Rohde recommends a 1 meg resistor between the 4046's charge pump
output and ground. This will help keep it out of the "dead zone" where
the effective PD gain falls to zero. I don't know why 33 pF should
throw your loop into oscillation -- that's likely to be worth
investigating.

> I have all of the required constants (Kvco = 415 KHz/volt, based on

> not 100% comfortable with that conversion.

Keep in mind that you're using a good-sized resistor in series with it,
so the charge pump current gain is effectively reduced. In a
third-order passive loop filter, R1 should be reduced drastically or
limited altogether.

I'd recommend downloading Dean Banerjee's PLL book "PLL Performance,
Simulation, and Design" from the National site. You can also buy it
from Amazon if you want a hardcopy. It was pretty enlightening when I
was climbing this particular learning curve awhile back.

2703. Spring Cleaning: here's what's left...

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-08 01:19:10 UTC
From: sparky@cet.com
Message-ID: <3cb0eefb.14627790@news.cet.com>
Source record: 44947
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.swap

Cleaning up the shop and here's a pile of junk that's collecting dust. Everything is 'make-an-offer'. Email me with any questions or if you need a pic. I may trade all or part for a decent HF general coverage receiver. Whatever the offer, any personal checks must clear before I ship.

==========

* Heathkit IG-72 audio signal generator;
* Hickok model 121 (cardmatic) tube tester, includes cards for 322 tubes, approx 50 lbs;
* O-scope, Telequipment model S54A (doesn't work, no power); 20 lbs;
* Power transformer, Marantz. 8VAC, 68.5VAC, 73VAC (low current), should easily power a 300W audio amp; 17 lbs;
* Power transformer from ARC PS; 117VAC 7 step primary; secondaries: 315 - 415VAC; 66.0 - 86.4VAC/CT; with matching chokes, and with cap for LV winding; total weight 15 lbs;
* DY-9/ARC-1 Dynamotor, 8 lbs.
Input 26VDC @ 4.0A, output 360 VDC @ .135A continuous,
Input 26VDC @ 7.5A, output 310 VDC @ .355A intermittant;
* One 1000' spool of Belden 9311 (RG-58A/U);
* JVC model 3050, AM/FM/PB, 3" B/W TV, w/AC adapter, only defect is the antenna tip broken off;

==========

The following is a bunch of parts that were mostly scrounged from dead radios. Some are real antiques. The parts will be sold as a lot. A small goldmine for the homebrewer:

* Several dozen pots, rotory and slide types;
* A couple dozen tube sockets, octal & min, a few ceramics;
* 31 large crystal sockets, 19 ceramic;
* Small box of vari-caps, up to 400pF, air & mica, many trimmers;
* Large homemade dual vari-cap (seperate shafts, and pretty well made), 400pF each section, 1/8" plate spacing;
* A few small audio & power transformers, most specs unknown;
* A small box of selenium rectifiers, specs unknown;
* One dozen meters, a couple larger ones too;
* A bootboxful of various coils, switches, knobs, assemblies, etc;
* Hundreds of tubes, all pulls. Several shoe-boxes full of miniatures, some compactrons, and here's a list of everything else that I'm willing to part with:

1A7 1Q5 1N5x2 6A7 6AC7x2 6BG6 6BQ6GA/6CU6
6D6 6F6-G 6H6 6Q7-G 6SA7-GT 6SK7 6SL7-GT
6SN7-GTA 6SQ7-GTx2 6V6-GTx5 6146x4 6146B 12DQ6
12JB6A 12SL7-GT 41 80 7984x2 4X150Ax2

End of parts lot. I have other parts in the shop if you can think of anything specific that I can add to the lot, like chips, connectors, crystals, etc. I will not add any RF power transistors or any more tubes, so don't ask!

pay attention to the supply filter to the VCO, a suggestion would be a NPN
series pass transistor with 47uF on its base to gnd (try BC849C)
and say 10-22k from collector to base.

Emitter to VCO.

Collector to supply in.

wide tuning VCOs only need microvolts of ripple to produce 100's of Hz of
deviation.

Also try to model the loop filter to keep filter resistor values low, if the
PLL has a high current charge pump setting , use it.

That's pretty much what I've done. The VCO has its own dedicated
emitter-follower supply.

Looks like we're going with the GALI-5 as a replacement for the ERA-5.
The last batch of ERA-5SMs I got in had a strange tendency to
oscillate... at about 3 kHz.

Hmmm... I am curious. My understanding is that MiniCircuits uses the
same chip as the Stanford Microdevices, just repackaged.

Last time I looked, they had pretty much identical parts with the same S
parameters.

Anyone know for sure ?

>

As I recall, with extremely high sensvitivity VCOs there is an additional
problem due to the wideband noise floor of most op-amps.

This extends far beyond the loop bandwith and it is part of the reason
good charge pump filters may be a good choice.

Granted, in a charge pump, you only get down to the inherent noise
contribution of the resistors in the integrator R/C but it DOES filter off
of the wideband noise from other sources that are beyond the loop filters
bandwidth.

Of course, there can easily be other things that limit the noise floor so
that the contribution of an Op-Amp loop filter may not matter. There are
so many things to consider it's hard to say where the noise floor is coming
from in many synthesizer designs.

Hi Joe and ebverybody who replied,
Thank you
I will try to find out if these things are available here.
Dave, no , I will not go there. It is not my intention to be a problem
to anybody. Thank for the warning.
Thanks Clive, I will try out these wireless headphones to see if I
could get 100m range.
Thanks Mark for the 100Mhz tip. No, the neighbours will not be upset
about rifle shots. They will be informed beforehand so they could have
the opportunity to check that one do not collect antything else except
jackal. The whole operation must always be totally above board as far
as the farmers are concerned.
Thank you all again.

I have a nice hinged top steel cabinet. It is 9 in high, 11 1/4 wide and 11 1/2 deep. The sides are vented and the back is solid except for the lower 3 in which is open for access to a chassis (chassis not included). There is no front panel but a
9 X 11 1/4 piece of sheet metal or aluminum would fix that. It is in great shape but could probably use a coat of paint due to it's 40 - 50 years of age (been in my attic 25 of them).
I'll ship and pick up the freight any place in 48 states, $25.00
Drop the RX320 to reply via e-mail

Yep. The usual practice is to add a final RC integrator between the opamp and VCO. In my case, I used an 82-ohm resistor and a 0.1 uF/100 pF combination. Without it, you can definitely see the effect of the opamp's noise. Fortunately the OP-27 doesn't seem to mind the extra load capacitance....

> temperature is true, but I have been wrong before.

Beta does increase with temperature. Just look at the characteristic
curves at 60 deg celcius. Incremental change in base current makes for
larger collector current changes at 60.

Bipolar transistors are usually designed and characterized for a given
application such as linear or non-linear operation. This is not to say
that you can't use either in a particular application, it just makes it
harder to design the actual circuit. As far as stability is concerned, I
didn't see the first posts, but I'm guessing that you are using the finals
in the common emitter mode. A cheap way to get more stability and better
linearity is with negative feedback. You can put some small value of
resistance in the emitter circuit with no bypasses on them. This will
reduce your gain, but you don't get anything for no price. Depending on
your collector current I would calculate the emitter resistor to be enough
to give you about 0.1vdc across it. You may also need to bump up the base
to ground resistor a little to bring the base bias up to compensate.
Experiment. That's what homebrew is all about.

73,

Steve WB4CZR

RF is a real pain.

There is a section in the ARRL Handbook explaining some of the basic principles, with an example to show how it can work.

There is also a lot of recent literature on circuit board design for Electromagnetic Compatibility that includes many of the same ground-rules.

After that, it's the same for everybody: actually doing it, and gaining practical experience.

I'm assuming that you want the noise generator to mask the noise in your
place rather than doing something which will expose you to nuisance laws or
malicious interference enforcement actions.
While you could design and build an audio noise generator, try the simple
way first - set an unmuted broadcast FM radio or an unsquelched V/UHF
amateur radio to an unused frequency and increase the audio until it drowns
out the neighbors noise.
You could also try experimenting with active noise suppression by sampling
the incoming noise and inverting it to cancel it out as it enters your
place.

Talking of these 433MHz modules: I had an idea I wanted to pursue and would
welcome input
I'm trying to monitor wildlife activity at night using a small B&W video
camera. At the moment, I'm simply recording it on video-tape with a VCR, but
as this is in the garden shed its not such a good idea. In any case, I'd
rather record onto the computer HDD. The distance from camera to computer is
around 50metres. I was thinking of transmitting it with a 433MHz Rx/Tx.
Would this be feasible?
Regards BruceC

2723. First project/ first radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-08 16:22:09 UTC
From: Matt <mthomas@biocontrolsys.com>
Message-ID: <3cb1c2e9$1@news.nwlink.com>
Source record: 44965

Greetings, all,

I'm looking for a first project(s). I recently got my technician's license, but still have no radio. It seems every time I'm ready to go out and get one, some unexpected expense comes along and eats up my radio savings. So I'm looking for a project for a transmitter and receiver (I'd be perfectly happy if it worked only for code) that is either inexpensive or can be built over time as money becomes available for parts. Projects for any other equipment I'll need will be appreciated, also. I spent a few years doing computer repair, so I know how to solder and can do so on relatively small parts (1mmx2mm fuses, small wires, LEDs, etc.). Of course, there are still tons that I don't know about building radios or electronic equipment. If there is a good book or website that would lead me through this (preferrably while explaining why it all works), I'd appreciate a point in that direction. Building stuff and figuring out how it all works is the real reason I got into amateur radio, so any help is appreciated.

73,
Matt

Hi Matt,
For VHF gear, I would recommend the Ten Tec kits- or for hF for that matter.
Nice starting point, well designed.

On the other hand, some of the older 2M gear like Clegg, or early Icoms go
extremely cheap on E-Bay.

Do you want full motion video, or would something like slow scan tv work, where you are getting a photo every so many seconds? If you want full motion video, then how about hooking up a video digitizer to the camera which then feeds to a wireless lan port, with your computer also on the wireless lan. For even terrible looking video you use about 1 meg per minute with a very high compression codec, so a nights video will be the better part of .5 gig. For decent looking video compression you use 10 times that and for uncompressed video you don't have a hard drive large enough (about 12 gigs an hour), not to mention the 2 gig limit on some video editing tools, and the 4 gig per file limit on most 32bit windows versions.

Buy one of these home 2.4GHz FM video/sound links, the picture quality is very
good and 50 meters should be no problem with them.

>
In this case there will be a point where the expression -210 +
10*log(Fcomp=1 MHz) +
20*log(N=1000) is minimized. By my calculations it would be worthwhile to
make F(comp) as high as possible
Eg could one make the DDS frequency (say) 45 MHz with a crystal filter at
this frequency. The tradeoff would be that the DDS range will have to be
wider (this could limit filter types) and DDS spurs will probably be
greater. Also there will be practical limitations re the phase detector etc.
The phase det comparison freq could be 9 MHz (say) which would give a gain
of nearly 10 dB in phase noise over the 1 MHz figure

The catch is that the minimum N for any dual-modulus prescaler is (M*M)-M, or 992 in the case of the LMX2326 with its fixed 32/33 prescaler modulus. With a 10.7 MHz reference the R modulus has to be 11 or greater to meet this criterion at a 1 GHz output frequency. I've been using R=12 in my code since the receiver project I'm working on needs the synth to tune down to 940 MHz.

The ADF4112 allows you to select other prescaler modulus values, but my earlier experiments with Fcomps in the several-MHz range did not look good, i.e. more noise, less stability. I'll revisit it next time I'm playing with my ADF4112 loop and see if I can take some graphs. I've been having trouble reproducing some of my initial observations lately... for instance, I now seem to be getting the best results from loop filters designed by following Banerjee's equations exactly, rather than by fudging the phase-detector current gain.

==========
It all depends on the power requirements for your car based unit.

A laptop normally needs 19-20 V @ 1 Ampere. For this you can build your
own 12 --> 20 V DC converter.
But using a 12V-DC---> 230V-AC inverter ,using the laptop's AC power supply
unit might be an easier solution.
Whatever , ensure that the computer is only switched on with the car engine
already running .
Unholy spikes might damage the computer if already connected and switched on
before starting the engine.

Thanks again to all those who sent suggestions on how I could fix the instability in the final amplifier of my new 17 meter SSB rig.

Over the wwekend I moved the biasing diode and positioned it right up against the junction of one of the transistors in the final and the heat sink that is common to both final amp transistors. The leads of the diode were almost enough to hold it in place, but I used some tin shears to cut a little "flap" in the heat sink material and bent the flap around the body of the diode. So the diode is getting a "nice warm hug" from the heat sink. Some heat sink compound was added for good measure.

Improvement was dramatic. Not only do I not see the spurs that I noticed before, but the new arrangement keeps the final MUCH cooler than before. EA8/EI0CL on Tenerife said he noticed an improvment in signal quality (but we agreed that it could have just been conditions).

This a was indeed a very "cool" fix. It was fun to put theory into action and then see immediate results.

==========
Another way to AM modulate the above CW tx is to use a 7812 voltage
regulator enabling 12Watts input max with a signal transistor (low power)
between the reference leg of the regulator and earth, with appropriate
biassing.
Instead of the signal transistor you can try a small audio transformer
,enabling galvanic separation between TX and Modulator.
I have seen this done with microwave Gunn diode type of txes.

I share the groups frustration... BUT - it may be the mail. IT SUCKS.
I live near Pittsburgh, PA (USA). It took one package shipped to me, a week to the day it was shipped - to get here from New York. I sent a package 2nd Day Priority to California. It arrived 2 weeks and 2 days later. I'm now awaiting a package from Alaska which was mailed out on March 16th. I have yet to see it and it's been close to a month. I guess the iceberg went off course, or perhaps a runner broke on the dogsled or one of the dogs broke a leg.

So, please allow a few more days..... IF after the 30th day you don't get your goods, then I would begin a search either through the seller OR the shipping to see where it is. IF it shows he truly hasn't shipped, then that is another matter.

I've never dealt with this guy before so know nothing of him. But in MY business, I'm here alone. IF I were to get ill and not able to pack and ship, it wouldn't get done. Otherwise, most of my stuff usually goes out same day as our mail comes in at 10:30 AM and all mail/UPS leaves town at 4:00 PM.
However, I would at least try to e-mail to let you know the status. I try to always inform the buyer the day I received their money and a ship status with each order.

I've dealt with many in the radio news groups and on E-Bay so my record can be researched.......I sell new and used items usually as a clearance - AS IS.

Just my two cents as a business man and a "victim" of the mail system.

$1,000 starting price for a 22 year old kit. Too funny, but then again there's fool born every minute.

I saw an unbuilt HW-9 QRP rig that was at $750 the other day - maybe it went for more.

Hard to believe people through away that much money on this old, outdated stuff.

Phineas Barnum was absolutely right.

Just as an experiment, I put up an old GC-1000 'Most Accurate
Clock' on E-pay last week. It was missing its front cover, and I never
could get it to do more than blink a few of its LEDs at me and make a
little noise.

I started the bidding at $10, which was less than I paid for the
manual copy from the nice folk at W7FG. The description clearly stated
that the thing seemed to have problems, and was sold as-is with the
manual copy. I didn't expect it to go for much over $30, considering its
condition, even with the insanity that can claim Ebay bidders.

Within 24 hours, it was up over $70, and it ended up going for
$150+! The winning bidder was the owner of an instrumentation firm who, I
assume, was going to fix it up and use it.

Go figure...

John:

Thanks for the helpful suggestions. I found the National PLL book and read it yesterday.

I've made some progress. After spending a couple of days designing loop filters and measuring step responses, but without change in the spurs, I did an experiment.

I disconnected the VCO steering pin and substituted a variable DC supply, set to give around 1 MHz. What I found was that the army of spurious signals still is there, at 8 KHz. Hence my immediate problem is not the loop filter.

As you suggested, these spurs must be sneaking in via some other path.

My first thought was a path via inadequate Vcc decoupling. I added a second 78L05 to feed only the 74HC4046, decoupled the +12 unregulated input to the new 78L05 via 100 ohm R & .01uF disc & 10uF tant. No change whatsoever in the spurious level when run with the external VCO drive supply.

Disconnecting the 8 KHz reference into the 4046 phase detector removes the spurs, which serves as a second check that Vcc coupling isn't the problem.

Following a suggestion in a Philips tech note, I then tried softening the 8 KHz reference via a 1K / 100 pF RC network. It softens the edge, but doesn't change the spurious level.

I'm inclined to not suspect the ground, as my construction is on a unbroken copper PC board, with Manhattan pads.

So, while I've made progress, I'm scratching my head over the exact source of the cross-contamination. Somehow--internal chip coupling?--my 8KHz clock is modulating the VCO, with the VCO loop completely disconnected.

Dude, a couple years ago, I found the owner's manual to the original Apple
II at a thrift store for 50 cents, and sold it for $217 on eBay! The
winner paid with a company check from a sofware firm near Seattle, and I
have no idea why he (or the other bidders he battled with) wanted it so
badly. I was almost too embarrassed to ask him ;)

Sounds like the only two things left are the ground and the varactor control line. What happens when you leave the loop filter disconnected, but bypass the varactor tuning line directly to ground *at the VCO* with a 0.1 uF cap?

Here's what happens on the ADF4112 with an Fcomp of 3.5 MHz (again, this is untestable on the LMX2326 because of its minimum-N requirement):

http://www.qsl.net/ke5fx/misc/3mhz.gif

At Fcomp=7 MHz the loop breaks into oscillation, so I backed the comparison frequency down to 3.5 MHz.

If I had to guess, I'd say the OP27's gain-bandwidth product of 8 MHz is coming into play, causing the opamp to roll off the narrow correction pulses coming in from the charge pump. I'll add an OP37 (GBP=63 MHz) to my next Digikey order and see what effect it has.

John:

The spurs are still there when I bypass the VCO tuning line to ground
with the loop disconnected.

I built a second layout today, 74HC4060 & 74HC4046 only, to test for
possible layout problems. Both chips fed by separate 78L05's, Vcc
bypassed with .01 & 1.0 uFs, no parallel conductors, etc. VCO tuning
line connected only to an auxiliary variable power supply with 1 uF
bypass cap. Different chips from the first layout.

Same thing. No spurs with the 4060 running but not connected, but as
soon as I connect the 8 KHz clock line to the 4046 phase detector
input, the spurs show up.

Tomorrow, I'm going to build a varactor tuned Colpitts with an FET or
BJT and use only the phase detector portion of the 74HC4046 to check
if the problem is the VCO portion of the 74HC4046. That's my current
guess, at least. I have a few MVAM 108's and 109's in the junkbox so
the tuning diode won't be a problem.

I can't believe I'm the only person to run into this quirk with the
74HC4046, but I haven't found a reference to it in my library or on

the internet.

Thanks again for the ideas and assistance. More tomorrow.

On second thought, since I already have the 74HC4046 running, I'll use
it as the VCO and try a second independent 74HC4046 used only as a
phase detector.

Richard:

AM BC band spacing in North America is 10 KHz. Most of the rest of the world uses 9 KHz spacing. (There was a semi-serious suggestion a few years ago that North America convert to 9 KHz spacing to create more AM radio assignments, but it quickly went nowhere, as there is an embedded base of who knows how many millions of 10 KHz step-tuning receivers. Instead, we upped the top band limit from 1600 KHz to 1700 KHz.)

I'm making some progress, as shown in my other posts. The main spur problem appears to be caused by things other than the loop filter.

I didn't realize at first that you were using the 4046's built-in VCO.
Those spurs may be unavoidable in that case... just part of the tradeoff
inherent in an all-in-one chip.

Are you using the specified value of load impedance for the VCO? My
guess is that the more you load it, the lower the spur amplitude will
be.

```
Junkbox Surplus Parts for Sale as of 04/01/02
==============================================
NEW stuff!!

LM78L62ACZ Volt regulators, TO92 format 5/$3.00 10/$5.00

SMT2222's - Surf Mount 2N2222 NPN's - 200/$5
SMT4403's - Surf Mount 2N4403 PNP's - 200/$5

470pf 5% surf mount caps - 200/$5
1000pf 20% surf mount caps - 200/$5

9.8304 Mhz Crystals, 1/4 in tall - 50 for $7.50

27mH inductors with radial leads - 50 for $7.00

================================================

Caps - All new, old stock. No pulls.
====================================
NEW .1 uF Poly/Film caps - 10% 250v, new stock, paper tape, nice
long leads. These are not NPO and are made by S&M Components
50/$3.00 or 100/$5.00

.01 uF ceramic caps, 10% 100v brand new by Kyocera
50/$3 or 100/$5

3300pf ceramic caps, 10% 50v
50/$3 or 100/$5

1000pf blue mono caps, 10% 100v
50/$3 or 100/$5

470pf ceramics on paper tape, rated 5% (NPO)
50/$3 or 100/$5

12pf NPO ceramics on tape
50/$4 or 100/$7

Voltage Regulators
==================
L7805ACV voltage regulators TO220 case. 5 for $4.00
L7806CV voltage regulators. TO220 case. 5 for $4.00
LM7812T voltage regulators. TO220 case. 5 for $4.00

LM317T Adjust. Positive Voltage Regulator TO220. 6 for $5.00
```

Key/Headphone Jacks
==========
These are 3.5mm female stereo PCB mount jacks. Can be used in
ugly/manhattan building projects with no problems.
3/$1.35 (or send a buck and a stamp)

Transistors
==========
TP2222 plastic TO92 NPN - NEW PARTS (House brand 2N2222)100/$7 50/4.00
2N3906's plastic TO92. PNP - 50/4.00 NEW PARTS
2N3704's plastic TO92, NPN - 50/4.00 NEW PARTS
2N7000 MOSFET - 5/$2

IRF540's TMOS Power FET, N-Channel, 27A, 100v RDS(on) = .070 Ohms
http://www.onsemi.com/pub/Collateral/IRF540-D.PDF
for data sheet - $1.00 each.

BC847B - Surface Mount NPN's, general purpose
CBO = 50v, CEO = 45v, EBO = 6v, Collector Current Max = 100 mA,
electrical characteristic curves for this unit are the same as the
PN2222A, SST222A, MMST2222A, and UMT222A transistor. These are new
stock, on SM tape.
200pc/$5.00

Op AMPS, Comparators
==========
LM741CN - Single Op Amp, 8 Pin Dip, 4 for $1.50
http://www.hep.ph.ic.ac.uk/~hallg/Instrumentation/Data/LM741.pdf

BA4558 - Dual Op Amp, 8 Pin Dip, 4 for $1.50
http://www.rohm.com/products/databook/standard/pdf/ba4558.pdf

BA10324 - LM324 equiv Quad Ground Sense Op Amp 14 pin, 4 for $1.50
http://www.flint.co.uk/product/pdfs/FR3LIN.PDF

BA10358 - Dual Ground Sense Op Amp, 8 pin, 4 for $1.50
http://www.flint.co.uk/product/pdfs/FR3LIN.PDF

BA10393 - Dual Comparator 8 pin dip, 4 for $1.50
http://www.flint.co.uk/product/pdfs/FR3LIN.PDF

BA10339 - Quad Comparator 14 pin, 4 for $1.50
http://www.flint.co.uk/product/pdfs/FR3LIN.PDF

BA4560 - Dual High Slew Op Amp, 4 for $1.50
http://www.rohm.com/products/databook/standard/pdf/ba4560.pdf

Diodes
======
1N4148 - You always need these. 75 for $2.00 These are NEW.

Let me know if you're interested. All prices are post paid to the
USA, unless otherwise noted. I will ship to non USA addresses but we
need to discuss the shipping charges first.

It's also possible that a package that plainly says "Air Mail" gets into
a surface mail bag.

I've more than once had an "Air Mail" package arrive very late, with a
Customs stamp saying "Port of Dover".

I've tried several different VCO loads with similar results:

(a) TTL gate (7400 used as a buffer, looked at 7400 output)
(b) High Z load (FET follower)
(c) 1 K load (1K series R to 50 ohm spectrum analyzer input)
(d) TTL gate (7400 used as buffer, output of 7400 driving a 2:1
broadband transformer to see if ground loop between various
instruments connected to the test board. Spectrum analyzer connected
to the isolated output windings on the transformer.)

The stamp on my payment card says 03/08/02, so I'll have some more patience. I have some friends in Philly, we send stuff (music and such) from time to time, it used to take 1 to 2 weeks, didn't send anything to one another after sept. 11th. I still think it sucks, I can understand they check every package coming in, but the ones going out, if we over here think they pose a treath, postal service over here will check them. Inside Europe, it takes 2 to 4 days to get anything anywhere. It's plain paranoia and it doesn't make USA based merchants look good.

No one likes a price increase but frankly the US 1st Class Postal rate is the biggest bargain on the planet. For less than 40 cents you can mail a 1 oz package from New York City to Los Angeles and be wildly assured it will get there in a few days.

I ship over 150 packages a year via USPS and it's 50% better than UPS or FED EX and about 50% cheaper. I ship to Europe, Australia, and Canada on a regular basis with very very few mishaps.

Perhaps Steven should just stop ordering things from US merchants, I wouldn't be a bit surprised to find out his package has been sitting in Belgium customs for the last few weeks. Maybe he should trust the Afghani postal system instead. (YIKES)

Hey, a camel could ride the package over from afghanistan in less than 4
weeks. Perhaps I could stop ordering, but no really good surplus dealers in
europe. I don't criticise US merchants anyway, 4 weeks just is a long wait.

WOW - you apparently deal with a different USPS than I do.

For small packages (of the type I normally deal with), UPS is 3 times as expensive as the postal service, FedEx even more expensive.

But there is a HUGE difference. Packages sent UPS take a few days within the U.S., how many a few is depends on the distance, but it's predictable (I'm speaking UPS Ground of course.) FedEx delivers your package in whatever length of time you contract for. I've never known them to be any different. When you hand a package to the USPS, it -may- arrive at some random time later. Once in a rare while you get a pleasant surprise and it arrives at a time somewhat similar to what UPS Ground would have taken. More often, it's a lot longer, often inexplicably. A package mailed across the state is just as likely to take days as it does weeks. A package mailed across the country will take a week or more, how much more is anyone's guess.

But in my mind, the biggest difference is that UPS and FedEx both know where your package is, and so do you if you go look. If you hand a packge to the Post Office, you have no idea where it is, and they apparently share in your ignorance. If it doesn't arrive, you have no recourse. It's lost, and because you don't have any idea how long it will take, by the time you are concerned, it's way too late. It may suddenly arrive months, maybe even years later. You simply have no idea. If it's insured you may get your money back a long time, and a lot of hassle later. But frequently, the money isn't the point.

Unless I'm sending something of very low value, the extra cost of UPS is well worth it to me.

It may not be the fastest way to get parts but you can find some hard to find parts and some real bargain prices. It is not Newark or digikey with many employees. It is a one man operation. No secretaries to answer dumb questions. If you are willing to wait a little while you can save some money on some items. Clogging up the newsgroup with updates on how many days it takes won't get the parts to you any sooner.

I echo all the sentiments below. I've been through Postal Hell just involving shipments within the Continental U.S - twice in a months time. NO THANKS.. From here in, my preference is UPS..... I'll pay a little extra to know where my shipment is. I've never had any problems with them.

Lou/Tech@DP.NET

It looks like everybody has a different USPS. I'm here on a little
island offshore from Puerto Rico and its extremely rare for USPS First
Class/Priority to take more than 3-4 days to anywhere in the continental
US...coming or going. The Post office quotes something like 4 weeks for
Parcel Post to/from this destination and its usually only two at the
most.
Mail to Europe is equally as good. Small air packets to Western Europe
5 days either way. Surface packages 20-30 days.
UPS and Fedex don't even offer ground service here so I have nothing to
compare to. Can't see how they could be any faster. I've had TWO
different Priority packages reach mainland addresses in LESS THAN 24
HOURS !!! Don't ask me how.
I've sent several hundred packages in the past 3-4 years and never had a
loss or un-warranted breakage.
I just wish they'd quit jacking up the rates on Priority Mail. For
'radio-size' packages the cost has doubled in the past 4-5 years.
I think the USPS is great and I don't even work for them!

Hate to throw things away but have no use for a toridal wound transformer that
was salvaged from a large mobile linear.
How about $15.00 and I pick up the freight to any place in the 48 states???

Drop the rx320 to e-mail

Rob Mills ~~~

Hey - new catalog! Dated 04/09/02. I'm still sitting on my order (the money order is burning a hole in my pocket though). I think I'll try phoning again - it's $0.10 a minute for me (if he ever answers).

i need to construct a 1:1balun for my dipole, i have done the "choke-balun"
but i have some toroidal which i would like to use, any sugestions on how to
wound the toroidal (how many turns, what king of cable etc)

thanks in advance

==========
There are a number of good surplus dealers in Europe ; to mention 2 :

1) Mainline Surplus - Leicester ,England
surplus@mainlinegroup.co.uk

2) BACO - Ymuiden , Netherlands phone: +31 255 511 612 , fax: +31 255
517 664

RF components
1) Barend Hendriksen www.xs4all.nl/~barendh

2) Kent Electronics www.kent-electronics.nl

2787. PEV and PEP at 12 volts

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-10 23:00:44 UTC
From: jehancoc@pacbell.net
Message-ID: <a95870c1.0204101500.403bbe44@posting.google.com>
Source record: 44930

I am building an amplifier strip to take 1mw up to about 1w. I am using 4 driver stages with an IRF510 final.

I am seeing about 7.05 volts peak-to-peak into a 50ohm resistive load on the scope. Using the following formula, this would translate into about 125mw.

PEP = (Peak-to-peak/2*.707)^2/50

The IRF510 output circuit was borrowed from a CW amp. I rebiased the amp to run Class A.

Given the 12 volt supply, I won't ever see more than 12 volts peak to peak out of this amp, correct? That would translate into 360mw.

So how do people get more than 360mw out of a 12v supply without voltage doubles, etc.? I've seen a number of circuits that suggest this.

Am I missing something?

Ground/sea mail from North America to Europe use to take about 4 weeks
for me before 11 Sept 2001, and I find it now takes about 5-6 weeks.

Air mail can take 1 to 3 weeks, but since $10 USD can roughly send a
dozen QSL cards overseas, I would expect that your parts are being
shipped by sea.

I've seen claims tht he Beta increases, but I know that the minority
carriers increase with temperature. So the hotter it gets the less the
resistance differential between forward and back.

I use ten turns of RG-400 (teflon) on an FT-240-61 core. Works very well.
I use RG-400 because it is small with a large breakdown voltage.

Source record: 44940

You should be able to get at least 20v pk-pk with a 12v supply. Ideal would be a voltage swing from 0v to +24v. The +24v comes from the inductive kick from the output filter and the transistor supply choke. Connected directly to a 50 ohm load, you should be able to get at least 1w at 12v (20v pk-pk). It looks like you simply may not be driving the transistor hard enough.

To get more than 1w, a step up transformer is required so that the transistor can work against a lower impedance and develop more power. A the transistor output of 12.5 ohm is readily acheived with a 4:1 transformer to match this to the 50 ohm output filter. 12.5 ohms at 12v gives between 4-5w at 12v when driven to full 20v to 24v pk-pk voltage swing.

Currently, I am using two amateur radios for communicating: one is the Icom 718 and the other, strictly for 10 meters, is an older Realistic HTX-100. I have used the HTX-100 for about 5 years now and I just obtained the Icom less than 6 months ago. I am puzzled by something though that I was wondering if anyone could address- the noise blanker on the HTX is FAR superior to the one on the Icom. I am wondering why? The Icom was a lot more expensive and I just figured it would have a better blanker. It has AF DSP option, which I tried, and was disappointed. In every case on 10 meters, the HTX receives better due to blanked noise effectiveness.

I doubt I could internally modify the Icom's blanker for better performance so I am wondering if I could add an external, synchronous (or other ?) type noise blanker at the antenna input. I have read a few things about this type of blanker and, apparently by using noise generators, you can match the phase of incoming noise and cancel it out. Any suggestions for a blanker, either internal or external? I understand the synchronous type is better at lower Mhz, but will it work for 10/15 meters?

I believe the main sources of noise at my QTH are computer (of course) and pole transformer noise. The computer noise is easily solved (by turning off my monitor) but I have experienced the transformer noise for many years, and the HTX blanker always nullified it.

Appreciate any suggestions from the groups.

Thanks,
AB

2801. Re: PEV and PEP at 12 volts

Newsgroup: rec.radio.amateur.homebrew

From: Ricardo Martins <ricardo.martins@pt.uu.net>
Message-ID: <3CB53EDB.1D459B2F@pt.uu.net>
Source record: 44943

Into an pure resistive 50 Ohm load, max. power dissipation should be: P
= R*I*I
since current into load should be: I = U/R = 12/50 = 0.24 A
there P = 50*0.24*0.24 = 2.88 W

From the formula I used you power is: 0.994 W, if you put 10% error on
your mesure equipment it is round 1 W

It could be right and it could be wrong.. who knows!?

I have to ask, did you purchase the noise blanker for the ICOM? It is not standard.

2803. Pulse-width AM transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-11 14:27:37 UTC
From: "r.crowley" <rcrowley7@xprt.net>
Message-ID: <ubb7alendr4m63@corp.supernews.com>
Source record: 44945

Is this method used anywhere? With modern digital circuitry, it seems almost easier to do than traditional methods of amplitude modulation. (Assuming appropriate filtering to produce proper sine-wave output, not square wave!)

Is there any AM activity on amateur bands anymore?

2804. Sinclair Q-202G tuning

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-11 14:44:59 UTC
From: prentice@icomnet.com
Message-ID: <fb0353a.0204110644.408fd6bc@posting.google.com>
Source record: 44946

While attempting to tune one of these duplexers, I cannot get the "notch" to tune above the pass freq. on the lowpass cavities. I am trying to tune the cavities for 144.630, which they tune OK, and notch 145.230, which I cannot get an acceptable notch on that frequency. The same pair on the highpass cavities, but reversed, work fine (i.e. pass 145.230, notch 144.630). It seems some modification is needed to the stub(s) on the cavities. Any help or guidance would be much appreciated.

Prentice

2805. Re: Sinclair Q-202G tuning

Source record: 44847

Those duplexers came in two ranges. 132 - 150 mhz or 148 - 174 mhz.
The cavities will usually
tune both ranges but the loops (where the notch is derived) may not.
You may have the high
split unit and the loops may not tune that low. I don't remember what
they have for stubs on that
duplexer but they made one several years earlier that they called a
"hybrid ring duplexer". It had
a complete ring with cables and several tuned stubs on the ring. In
order to put it on the ham
bands you could put in some right angle elbow connectors to slightly
lengthen the cables and
stubs. It worked great. On the 202 though you may need to change the
coupling loops in the
cans.

Easiest to call Sinclair with the exact model numbers and they can
tell you how it was originally
built and what would be needed to change it.

As a note, see if you may have the high and low pass cavities
reversed. Some cavities the notch
can be tuned on either side of the pass frequency and some can only be
tuned on one side.

Alan,

Although I purchased the Icom used, it did already have the noise blanker,
which hardly makes any difference in noise level when activated (unlike the
HTX). The AF DSP was purchased and added later, but to me it is no better
than the already present blanker.

I don't quite understand what form of transmission you are trying to
describe? PWM is a defined form of modulation. It is no more
amplitude modulated than CW is. Indeed, CW could be considered a form
of PWM.

PWM is used in some Radio Control (RC) systems found in model planes
and boats, although digital systems are the most common.

SAVE your TIME, MONEY, and EFFORT!

That article, like every OTHER one I've read on the subject, involves LOTS of effort, money and
contortion - and leaves you with an amp that is a butchered monstrosity that will deliver about the
same output as a stock Heathkit SB-200 or Yaesu 2100B that can usually be bought for LESS than the
cost to modify the Dentron 2500...

According to the pointed to article, the BEST observed OUTPUT power AFTER modification, was 840
watts - MY Dentron 2500B will put out 2KW into my dummy load any time, any day! The swapping of tube
types proposed by such articles are HARDLY to be considered a valid "improvement", OR a reasonable
method to ressurrect a 2500B...

I *am* surprised that some enterprising soul hasn't tried swapping in the more easily obtained
572B's - they operate at the same voltages, current and drive levels as the 8875's, use the same
type and placement of cooling, and it LOOKS as though they would fit in the provided space. If and
when MY 8875's fail, I'd be inclined to try the 572B's - but NEVER tubes like that article suggests...

It very well may be that your ICOM "hears better" than the
HTX-100. If it "hears better" it will "hear" noise at a level
below what the HTX can "hear". End result: the HTX
sounds better - but it misses the weak ones that the ICOM
"hears".

On a quiet band, the pre-amps in my 746 are great - but if
the band is noisy, I find that turning them off makes the radio
sound much better. Bottom line - there may be more noise to
blank due to greater sensitivity in the ICOM then in the HTX.
I have neither of the rigs you mention, so I'm only pointing
out a possibility. For all I know, the HTX may "hear" better
than the ICOM.

Oversimplification: if you integrate a PWM signal with the appropriate
filter, you get a controllable amplitude level.

Easy but you have do a bit of abstract thinking and pray.

Take the file name, mla2500b.zip, and search for it using say Google,
http://www.google.com.

Results 1 - 7 of about 11. Search took 0.07 seconds

I could download it from:

http://www2.arrl.org/files/qst-binaries/

Source record: 44862

John:

I can report success. The layout with separate VCO and phase detector chips works quite well.

Other than harmonics of the VCO, all spurs are at least -65 dBc, and that's only one pair of spurs that I can cause to go right into the noise by slightly changing the wire dress of the 10 KHz reference. Everything else is below -75 dBC.

I received my 10240 crystals, so I now have real 10 KHz steps, and see very good lock up over the 480 KHz - 1990 KHz range.

I used a loop filter that I had calculated using the Philips datasheet, but could not get to work consistently with the other layout. There must be some wierd parasitic coupling in my original layout, some of which must be parasitics in the 74CD4046 chip itself, based on the partial-assembly measurements I made.

I haven't looked at close-in phase noise, other than with the spectrum analyzer.

Thanks again for the assistance. Next step is to build a low power transmitter and AM modulator.

Just carefully check the claimed power output AFTER the mods
suggested - and compare them with the 2 KW the STOCK Dentron's do -
THAT alone should convince you of the validity of the "conversion"...

There are FAR better ways to spend yer time and money than on a
"conversion" that leaves you with an amp the now only has about the
same OUTPUT as a stock SB-200 or similar amp that can be bought for
LESS than the cost of the conversion of the 2500B...

Many commercial AM broadcast transmitters now use this method.

There is lots of AM activity on the ham bands and quite a few are already
using PWM
to produce the AM.

Check www.amfone.net for an article on this.

Cool, sounds like you're pretty close to optimal with this design.
Nothing in the world wrong with making an educated guess at the
capacitor values and using pots to find the best resistor values, as
long as you have an SA and you know what you're looking at. You should
grab a copy of Banerjee's book if you plan to do much more
experimentation with PLLs -- he has lots of examples (some of which
don't even have typos).

If it sounds good in a receiver with a narrow CW filter, then you're
done.

The loop filter was one that I calculated, didn't have to make any
adjustments to it, other than adding one shunt C to reduce the noise.

I did download Banerjee's book and printed it for more detailed study.
Thanks for the reference to it.

I've been listening to it with the Racal 6790/GM that I keep in the
workshop. It sounds reasonably good, but will stick an attenuator in
the antenna lead to drop the signal level down to a more reasonable
level and tune around some more.

Something isn't right. The 3cx400 is reported to be equal to the 8874 which is identical electrically to the 8875, the original tubes in the MLA2500. What is it about the conversion that drops the power? It shouldn't.

If MLA2500 owners would use them a bit more carefully they wouldn't eat tubes. Of course it would help if the manual had instructed users to keep the grid current down to a VERY LOW value. Instead they allowed 100 mils, and that tube just won't handle it longterm. IIRC the specs for the 8874/8875 series show 4 ma grid current continuous. I have a MLAS2500, and keep the meter switch on the 'grid' setting. If anything changes that causes *any* observable grid current to flow I want to know about it-normal tuning is for zero grid current here. I've had this MLA2500 for over 15 years and the original tubes are still virtually as good as new. I like it because it is very compact for the power output and it covers all bands 160 through 10 meters, since it was built before the 10 meter amplifier ban.

SO, a quick and simple question - the "conversion article" claims a MAXIMUM power out of 840 watts
AFTER switching to the 400's - how much power can YOU get outta YOUR stock 2500B?

I can get 2 kw outta MINE - so I agree, something IS seriously WRONG with those 2500B conversions - so why MAKE the conversion for so POOR a return in efficiency - as clearly indicated
right in the conversion articles themselves?

Do you actually need the 'text' step? There are programs that you can
use to convert the mp3 freqs directly. If its a matter of being able to
single out what you're converting, most of these things have editing
features so that you can select certain portions of the mp3, etc.

While this conversion may work quite well when the desired CW signal
is the only signal in the recording or at least the strongest signal
in the recording, strange things can happen with psyco-acoustically
coded recordings, such as MP3.

These psyco-acoustical compression methods discards a lot of material
that the ear is not supposed to hear, e.g. due to masking by a nearby
strong signal.

Assume that there is a strong undesired carrier or CW signal at 3000
Hz and a weak desired CW signal at 3200 Hz, i.e. far less than an
octave from each other in the same critical frequency band, the human
might not hear the weaker signal and MP3 encoder might completely
remove the signal. Now converting this signal down by multiplying the
signal with a 2800 Hz sine wave (the "BFO"), the undesired signal is
at 200 Hz and the desired CW signal at 400 Hz, they are one octave
part and definitively in a separate critical frequency band and thus,
both signals are audible.

If the original MP3 recording with a high compression ratio had
discarded the "useless" 3200 Hz signal from the recording, it would
not be available after shifting down to a lower frequency. Thus, it
is very important to use uncompressed or lossless compression (e.g.
zip) recordings are used if some postprocessing, such as very narrow
band filtering or frequency shifting is used.

Eric,

>Its called class D
>
>> Check www.amfone.net for an article on this.

Not just D but E & F.

Most e3very AM broadcast transmitter manufacturer now uses PWM, or PDM,
some have gone totally digital.

The only AM transmitters not to use this form of modulator tend to be
those few made for low power, under 100w, such as those by Tesla and
LPB.

They use either low level and add a linear or in the case of the Tesla
they use Progressive Series modulation.

Mine is not a B model, but it never did output 2KW, more like 1.5,
which is the legal limit anyway. And I've tried a brand new set of Eimac
tubes in it with the output nearly the exact same 1.5KW. I used a
separate wattmeter and dummy load for the test. Internal wattmeters seem
to rarely be very accurate.

Certainly no argument from me, but if I was faced with buying a pair of
finals for it I might view it differently.
I still think the answer is to run the amp right in the first place and
not fry the final tube grids. This won't help after the fact, of course.

2837. Looking for Source to buy TSL236 Light-Frequency Converter

Nope, it's just the 'system'. On the established routes US Mail
service is quite good. It's the 'out of the way' destinations which have
a valid claim to 'snail mail' service. Who knows where a package goes
enroute?

I suppose you could hook the output of your sound card playing the mp3 to the input and use cwget to convert to text. It might be better if you have two computers if your system isn't capable of running the soundcard full duplex.

If the cw was originally machine generated, I have yet to see cwget not convert it. I use it to convert ARRL bulletins and my antenna/radio combo is far from good.
thanks, John.

In reading a lot on the Icom reflector, I have found consistent comments indicating the problem is Icom's engineers simply do NOT know how to build a really effective noise blanker! I currently own a 756PRO and it can't hold a candle to the blankers in other radios I've owned including a Kenwood 940, Ten Tec Titan and Yaesu FT-1000D. It's probably the worst HF NB I've used. I have not used the Icom 718 but doubt there is any reason to believe it would be the one exception in their line.

I have seen some incredibly good blankers in RS products.

Here's a few that I've tried: CoolEdit, Audacity, WinADR, ACMStation.
The features vary a bit...CoolEdit is by far the best. Trial versions
can be found at the places like shareware.com, etc.

Ed,

No doubt you realize the irony in these statements, since the RS stuff is built in Japan. The difference is .. communication. I work for a company that is owned by a Japanese corporation. The product is designed here, but whether the end result is close to the intent is a matter of communication between the US and Japanese divisions. This is the key, and is not a simple matter. Put simply, unless you can get them to understand what you want, you have a zero chance of getting it.

I'll try. I have some MP3 CW recordings which are a mix of CW at different frequencies, that is, they change frequencies every so often. I would like to make them all the same frequency. A frequency of my choosing. I thought if I could get them back to text format, I could use a program I have for making them into new MP3 recordings and they would all be at the frequency I wanted.

Hope this helps.

Thanks and 73,

True for Kenwood too. I have an old Uniden 10 meter rig which has the
finest noise blanker I've ever seen for ignition noise. I've compared
it against a half dozen Icom and Kenwood rigs and it beats them all by
far.

Designing noise blankers must be part science, part art and part magic.

John --

I'm not understanding. Suppose I have a transmitter that is putting out a true on-off pulse width modulated signal. You mention an "appropriate filter". Are you talking about this filter at the transmitter end or the receiver end? And if I do modulate a transmitter with PWM, what does a standard AM receiver using either envelope detection or some other scheme see? Is it transparent to the receiver the modulation technique or is it chopped at the other end?

Oh, I get it now. You're speaking in terms of actual audio frequencies
instead of sampling freqs.
Hmmm, I know you can fiddle with the sampling rates and stuff to slow
down/speed up a recording but I can't think of any easy way to
'calibrate' the random tones to a standard norm.
I have seen encoders that will read text and send CW but can't recall a
name. Ones that convert CW to text are pretty common as I see them
mentioned quite often. Some of the guys on rec.radio.shortwave use them
for copying CW, RTTY, fax, etc. You might ask there for some
recommendations.
Good luck with your project.

From the Svetlana 4cx400 conversion notes, and
some research into the 2500B specifications:

2500B power transformer is good for 750 W CCS. With 2 x 4cx400
the 840 W reported is single tone PEP translates to 595 W RMS
In consideration of the typical 50% over CCS that one can usually get out of
a transformer in ICAS (1120 W) this translates to about 52% efficiency, and
agrees with most CW specs for ham amps.

The GI7B conversion is reported to yield 1200 W out (two tone)
or 600 W RMS. Same power!

I bet the 2 KW output reported, corresponds to voice peaks and
not the single tone it is compared to. Voice has a higher peak to average
ratio than two tone so 2 KW peak seems pretty reasonable.

I suspect 2 major issues create lower than hoped for output in the conversions under discussion -
first is the class of operation they appear to be operating in - which seems to be AB1/AB2 - both
down in efficiency compared to the more common class B operation for linear amplifier operation...
SECOND, is the likelihood that the final tank circuit needs significant tweaking to comphensate for
the different plate impedance of the substituted finals.

2 OTHER inherant, potential issue with those conversions, is the unsatisfactory adaption of cooling
system from the 8875's to the vastly differing system needed for tubes like the 400's and 800's -
the 8875's survive quite nicely with low-pressure, high-volume airflow, while the others desperately
need both high flow rates AND decent flow PRESSURE for adequate cooling under power levels the MLA
2500 was designed to operate - but which the specified muffin fans are NOT capable of! NEXT on the
list is the specified need, common in grid-driven amps, for LOW-LEVEL drive in those conversions,
which while possible in most late model transceivers, is VERY likely to lead to unwanted impurities
in output as various audio/electronic impurities are NOW being brought up much nearer to the level
of the DESIRED signal for amplification - much like a hifi driver with low output, when the following audio amp is turned up to comphensate, bringing an increased hum and distortion level WITH
it... At the very LEAST, a power deviding T pad SHOULD be used in these cases, rather than merely
relying upon turning down driver output as the only solution.

And finally, we entirely agree on proper loading and driving of the stock 2500 amps - I operate mine
on 220 volt mains, use 50-60 watts drive, and normally show 1250 watts out on an instant reading
peak wattmeter, and RARELY see the faintest trace of grid current - tho it WILL load MUCH higher if
I so desire. It IS a shame these amps don't use tubes more easily obtained - but SO FAR, the
suggested "conversions" leave MUCH to be desired to match the abilities of the stock MLA-2500's

In response to a fella questioning my reference to power output of the Heath SB-200 and Yaesu
2100B - as well as some issues to power supply capabilities - my response...

You're entitled to your opinion - but *I* have actually owned and operated the SB-200, a pair of
Yaesu 2100B's and a Dentron Clipperton L - BOTH amps using a PAIR of 572B's were capable of a best
key-down power out of over 800 watts into a dummy load - the Clipperton, with 4 572's was capable of
over 1600 watts out... NOW, THAT'S actual experience, NOT theory or assumption!

Power supply capabilities, or tube charts are NOT the issue here - the efficiency and ACTUAL
operation of a proposed MLA 2500 "conversion" IS! And I steadfastly maintain that the suggested
conversions are NOT getting the best/most out of the specified tubes, or the original capabilities
of the MLA-2500 - and THAT is what this thread is about!

Hi Ed

I hate to admit it, but I have to agree with you as well.
I have an HTX-100 and will use it rather than a Kenwood HF rig, unless the band really gets rough.

I have inline with the HTX100 a very old HyGain Receiver Preamp from the hayday of the CB boom as well. I have found that by keeping the Receiver Gain on the HTX100 turned down to about 1/2 and using the external pre-amp I can pull in stations that fly right by the Kenwood. The HTX100 hears them without the pre-amp with the gain cranked up, but the pre-amp seems to keep the noise to a minimum and brings up only the signal itself, in most cases, needless to say, there are exceptions. I also have a DSP from RS, it's great on CW but almost useless on sideband.

When I take the HTX100 on the road, the NB filters out every speck of ignition noise, including that from other vehicles and trucks around you.

The only NB filter I have found that works better than the ones used in the RS ham gear, was the 'crystal lattice filter' that was found in many Lafayette R&E Chicken Band rigs.

I see a little confusion on PEP and average power. If you put in full carrier (or single tone) and
get 1000 watts output that is 1000 watts average power. Same power on cw. It is also 1000
watts PEP. If you switch to SSB and drive the audio up to full power out you are running 1000
watts PEP. Now the PEP may be slightly higher because the power supply will not sag quite as
much on SSB as it does on CW. You may actually get another 150 or so watts PEP out on
SSB because of the power supply. Your average power out with voice will be in the area of
150 to 300 watts depending on voice characteristics.

With a two tone signal the same amplifier will still put out 1000 watts PEP. The average power
will be 1/2 that or 500 watts average.

The best way to compare outputs is with carrier (single tone). This gives all the power out that
the amp can do. Less a little of course for power supply sag.

Be careful of watt meter readings when comparing amps. All watt meters are not created equal.
I see some claims of 800 watts out of an SB200. If it would in fact put out that much I would
think the 3rd order products would be pretty bad. You would have to overdrive it to get that
much power out.

> it against a half dozen Icom and Kenwood rigs and it beats them all by
> far.

Exactly my point, Bill. I can't figure out why the regular HF manufacturers like Icom and Yaesu don't design adequate noise blankers. This 718 for example was over $500 while the HTX was obtained used for under $100. The HTX has a far superior blanker. I've tried AF DSP, but the blanker is still better. IF DSP I think would be a different story though, but I think excessive cost would be an issue.

I'm now checking out a synchronous noise blanker design on the web. Looks promising, but according to the info. I've read, works best only on the lower bands, especially at 160 meters and lower. I'm also checking into a phaser that samples noise and deletes it by inverting and cancelling. Both of these designs attack the noise before it enters the rig and, at least to me, show promise.

Make shure you use the same instrument to measure the power... into the same
dummy load...

>first is the class of operation they appear to be operating in - which
seems to be AB1/AB2 - both
>down in efficiency compared to the more common class B operation for linear
amplifier operation...

The MLA2500 is operating AB2 !! that is the common class of operating zero
bias tubes !!

>SECOND, is the likelihood that the final tank circuit needs significant
tweaking to comphensate for
>the different plate impedance of the substituted finals.

On same platevoltage and platecurrent there is no difference in impedance at
all !!

>
>2 OTHER inherant, potential issue with those conversions, is the
unsatisfactory adaption of cooling
>system from the 8875's to the vastly differing system needed for tubes like
the 400's and 800's -

provided adequate cooling, there is no reason for lower output, of course
the 4CXs need some pressure..

>it... At the very LEAST, a power deviding T pad SHOULD be used in these
cases, rather than merely
>relying upon turning down driver output as the only solution.

best is to let the driver work into a dummy load at the grid through an
attenuator

>> > AFTER switching to the 400's - how much power can YOU get outta YOUR
stock 2500B?

2 KW out means > 3KW in -----> plate dissipation > 1 KW, the 8875 is
limited to 300W by Eimac..
I suspect that also other parameters are exceeded:
max Plate Voltage is 2200V, maximum plate current 0,35 A , data for one tube

or, which is more likely, the measurement is wrong !!

>> > *I* can get 2 kw outta MINE - so I agree, something IS seriously WRONG with those 2500B

would be interested to see it running in a rtty-contest with 2kw out :-)

>> > conversions - so why MAKE the conversion for so POOR a return in efficiency - as clearly
>indicated
>> > right in the conversion articles themselves?

There will be nothing wrong with the conversion, the 8875 has the lower plate dissipation,
so with the higher dissipation of the 400s there is some safety margin.

You cannot expect to get more output then the amplifier was designed for.
The plate transformer and the plate output components are designed for probably not more then 1KW keydown output

Repaired already a couple of MLA2500s from contesters, who fried bandswitches and coils..

(output measures with bird equipment at 220 Volt never more then 1300 Watts)

I notice a large and rapidly increasing number of postings which are offers to sell or buy one item or another, or to advertise an ebay auction item.

Aren't there newsgroups that are more appropriate for this, like rec.radio.amateur.equipment and .swap, or rec.radio.swap? If not, we should start a newsgroup for the purpose. I find it annoying to have to fish through the ads to find the postings about homebrewing, but maybe I'm a voice in the wilderness. I'd sure like to see the trend reversed before the ads completely dominate the group.

Amidon's FT series parts are ferrite, and are mostly equivalent to Fair-Rite or Magnetics products with the same part number. T series parts are powdered iron, and correspond to MicroMetals product designations. To substitute a ferrite, look at the initial permeability, and find a core with about the same value. Then, if necessary, you can stack cores to get about the same impedance per turn squared. Within reason, you can also alter the number of turns to get the same impedance. You shouldn't use a core with a very different initial permeability unless you understand the tradeoffs involved.

You should never substitute a powdered iron core for a ferrite core, again unless you have a very good understanding of the differences. And even then, a reasonable substitution is usually impossible. Low frequency powdered iron cores are used for high flux density low frequency applications like transformers for switching supplies. High frequency powdered irons are used for inductors in tuned circuits, where Q, temperature coefficient, and high flux level capability are often important. So making a good substitution is tricky. I'd recommend trying a candidate core, then measuring the inductance and Q to see if it's adequate for the application. Ferrite, not powdered iron, is used for broadband RF transformers like the ones in HF power amplifiers.

I expect you're right. My straight MLA2500 will do 1425 watts keydown
carrier into a dummy load operating on 240VAC. No way it'll do 2KW. But
I didn't check it at PEP.

Agreed. The only ham amp I ever owned that had a PS that *wouldn't* sag
a good bit under full carrier load was the 4-1000A I built myself using
a plate transformer from a Gates AM broadcast transmitter. Most will
drop a few hundred watts, which will be preserved pretty well on SSB
peaks on normal voice.

I've never owned the Dentron but I know two fellas who got them when
they first came out. They both easily did 2200 watts out keydown into a
dummy load, measured with a Bird wattmeter, one was using 110 vac. I
guess its only fair to mention that neither lasted very long :-)

Of course, we're talking here about what they are CAPABLE of in extreme go-for-broke output - NOT
what we recommend for normal, fulltime operation - but SOME like to fall back on extreme scenarios
as ridicule fodder, rather than recognize the INTENT of the measurement... NO, I not talking about
YOU or Dick...

Along these lines, my response to another behind-the scenes Email, refering to test procedures *I*
mormally use...

"READ my lips - as stated in my last message to you I test with maximum key-down CARRIER in CW mode
on the exciter - SSB mode on the 2500B - when tuned for MAXIMUM carrier output from the amp, I get
the stated power levels. I *also* see the SAME or slightly BETTER output on voice peaks when
switched to SSB... On the SB-200 and FT-2100B, usually approached 1 KW peak outputs on SSB into a
peak-reading power meter - and while some might NEXT attack the accuracy of my meter, it HAS been
checked against other quality meters, and is HARDLY off by the 50-60% it would have to be to match
critics claims... As far as my MLA-2500B is concerned, at maximum output, I can easily see 2KW voice
peaks on SSB..."

I might mention that the SAME wattmeter indicates 100-110 watts out from my TS-570, and 100 watts
out from my IC-746 and IC- 706IIG - It indicates 1600 watts out on my Amp Supply LK500NTX - all
under the SAME test procedures - so it hardly seems my meter should be TOO suspect to other that the
extremely desperate...

I repeat - I'm SURE the 400 and 800 tubes referred to are EXCXELLENT power producers in circuits
DESIGNED to optimize their performance - but I maintain that the MLA 2500 conversion articles under
discussion here are NOT obtaining that capability!

My K2 has a pretty effective noise blanker when I run it in the car. In
fact,
very effective.

2866. Re: Pulse-width AM transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-12 22:11:01 UTC
From: Bill & Suzie Whatley <spud286@attbi.com>
Message-ID: <VXIt8.899$G72.773@sccrnsc01>
Source record: 44808

PWM is used because "high level" modulation can be achieved with far less modulator power than the old system of plate modulation. Technically, it is a series modulator (no transformer) which has much higher efficiency that the old class A modulators.

The filter is in the PWM modulator prior to coupling into the RF amp of the transmitter, not the receiver. The RF envelope looks just like regular AM at the output of the TX.

From: Rich Griffiths <richgrif@one.net>
Message-ID: <3CB763A7.D1BB3EE9@one.net>
Source record: 44809

The power out depends on the supply voltage and the load presented to
the amplifier. Power out is approximately:

P = V^2 / 2R

R is rarely made to be 50 Ohms. A transformer and/or other matching
circuitry will convert your "load" impedance into whatever you want the
amp to see. For transistor power amps, that's usually only a few Ohms.

So if you want 36 Watts out, you need R = V^2 / 2P = 144 / 72 = 2
Ohms, and you have to make a matching network that transforms 50 Ohms
<=> 2 Ohms.

Back to the conversion!!!

2 x GI7BT triodes, not expensive or complicated.
Tubes are $25/each, delivered, NOS ex Soviet military.
I machined some mounts and will sell for $32/each to anyone who
doesn't want to make their own. So there is $50 to $114 in parts.
Additional parts. Filament transformer (GI6B/7B/7BT is 12V)
2 x silicone rubber chimneys, a biscuit(tm) blower from Allied,
fits where the old blower went, about 2 sq. feet of 0.032 6061T6
Aluminum and some screws and pop rivets.

The clean, full output, SB200 will fetch $350+ on ebay.
Just what I'll have in the MLA2500B when the conversion is done.
3db and 160m on an even $ swap!

Here is the tube:
http://www.nd2x.net/gi7b.html

HMMmmm - the pointer you provide seems primarily aimed at UHF operation of the tube, and in severely
pulsed operation - the plate dissipation looks good, as does the price and general design of the
tube in comparison to the 8875's. Sure would like to see a HF power chart, and the claimed 650 hours
tube life seems short, but that is probably at full frequency and power levels - dunno how that
would compare at HF with the 8875's - disregard my Email question concerning the Russian tubes -
this post has answered my questions..

Thanks.

As long as the ads at least have something to do with homebrewing,
and/or come from people who otherwise contribute to the group, I'm fine
with them. I've bought stuff from people via the r.r.a.h. newsgroup,
and will continue to do so. Unfortunately a lot of the ads don't meet
either of the above criteria, and there's only so much that can be done
to stop them.

What needs to be avoided at ALL costs is the type of Vietnamesque
flamewar that has consumed groups like rec.antiques.radio+phono, where
the number of posts debating the type and quantity of acceptable ads
exceeds the actual number of said ads by at least two orders of
magnitude.

I tend to post a brief link on here when I'm selling a piece of test
equipment on the 'Bay, and haven't really had any complaints. In some
cases, like the functional but somewhat-less-than-cherry Tek spectrum
analyzer I'm about to list, there are some real homebrew-related
bargains to be had.

I imagine they spread some fairly trashy signals, too. Once the amp is
driven past the linear portion of the grid curve average output may go
up some but it sure ain't linear any longer!
Another aside- I always consider the difference between average power
and PEP on most ham amps to be the difference in power supply droop at
keydown vs voice signal input which is often a few hundred to several
hundred volts. The droop usually doesn't show up with voice signal
input. If no droop, no difference.

Probably a slip of the key, but the formula you used gives average power
not peak envelope power.

Taking the p-p value and dividing by two gives the peak value. Multiplying
that by 0.707 (assuming that it is a sinewave and not some complex
waveshape) fives the rms amplitude of the wave. Squaring that and dividing
by the value of load resistance across which the voltage was measured gives
the average or root-mean-square power.

Apart from that, though, the real answer to your dilemma lies in impedance
matching, specificially with step-up transformers that can increase the
peak-to-peak voltage at the output load.

Ed, while I cannot agree so strongly with your conclusion, I will admit that my 765 and PRO leave a bit to be desired in the NB department. As far as Icom is concerned, the best noise limiter or blanker I have ever had on a receiver - since 1945! - is the one on the little IC-730 that I use for mobile service. It can totally remove ignition noise that is S7 or more on the meter. Couldn't belive it, first time I tried it. So, it is not a generic Icom failing.

I think that what is happening with the NB situation is that the operation and eventual effectiveness of the blanker has to be balanced off against other performance properties of the radio. I think that we can all agree that Icom engineers are just as competent as any others at designing HF amateur radios, so they are doing what they do for sound reasons, just not very obvious reasons. I suspect that they can design a NB that will handle anything you can throw at it with almost perfect operation. But, what has to "give" elsewhere in order to allow that degree of performance?

Engineering such complex products as our modern transceivers is never black and white - I suspect that even most shades of grey have been worn out by now! <:}

One nasty problem in noise blanker design is the need to have a chunk of circuitry before the narrow crystal filter. This circuit has to delay the noise pulse on the signal path long enough for the noise detector to trigger and shut the signal path down. A few hundred picoseconds would be nice... Maybe even longer to get a really good performing noise blanker. A microsecond or so time delay would help a LOT.

==========

In order to get good strong signal handling most modern designs place the narrow filter as close to the front end of the radio as it can get... Often right after the mixer. This provides better strong signalling performance.

On the other hand, the crystal filter tends to 'ring' on the high energy noise pulse. Also, the phase shifts and group delay on the sides of the crystal filter tend to broaden out the noise pulse, frequently making it very difficult to have a noise blanker work on this broad and long pulse.

So, as a few people have suggested, it is all a matter of compromises in design. The trend has been to make better dynamic range radios and the engineering required to do that makes it difficult to add a really good noise blanker.

Many of the CB rigs had quite a bit of circuitry in them which slowed the main signal path down... They also usually have relatively lousy strong signal handling ability. These CB rigs were optimized for use in cars and such, focussing on low cost.

They also tried to make them handle ignition noise blankers and in the tradeoff they overload much more easily in a strong signal environment.

==========

I am not saying it can't be done, but rather that making a radio with good dynamic range AND a good noise blanker are almost contradictions. The designer can do one or the other. Both at the same time takes CAREFUL engineering and adds quite a bit of cost.

I have an Icom 730 that I used a few times in a VW squareback, which had terrible ignition noise that even the 730 couldn't tame. I built up a little circuit that fired a one-shot from the ignition coil primary, like a tach does, and fed that into the noise blanker circuit of the 730. Did wonders.

[Side note: I gave my "Antenna Basics" talk at Arkiecon last week. At one point, I ask the audience to vote for how many dB they think there are in an "S-Unit". The first choice was "less than 2". A hand went up in the back. Then 2. Same hand. 3. Same one, at every choice, all the way up. . Hm. . . somebody in the audience Has A Clue. Turned out to be George, who introduced himself after the talk. I enjoyed meeting you, George!]

Probably true to a degree - but all things being equal which would YOU *honestly* choose - an amp
easily showing 2 KW OUT, key down, or one showing only 1200 watts out, under the same test conditions... No fancy footwork now, just a quick honest answer! <grin>

After all, MOST amps that will put out 2 KW at full grunt, will likely put out 1.5 KW pretty easily
and cleanly, all day long...

Hey Ed!!

I run my K2 in my old Jeep now and then. And my Jeep needs a
radio license! It even tears up 2M FM. But the one mode on the
K2 NB takes it ALL out. I mean ALL! I've never heard something
work so well.

Next best the Uniden uPD858 chassis SSB set as used in the
TRC-449. That seemed to be REALLY effective. The 424 was
ok for an AM rig, but not like the 449 (and the other two variants,
the 457 and 458, which were pretty much the same rig, only the 457
and 458 had an extra can and filter in the IF.)

Roy, et al,

My understanding is that the original intent for the mentioned news groups is as follows: SWAP site is for buy/sell/wanted/trade and the other sites are for discussion/questions/replies.

While I don't care to sift through the FA ads as I can go there to look for an item if I wish, it is unlikely that they will go away.

2882. Re: Pulse-width AM transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-13 02:26:27 UTC
From: martin@okstate.edu
Message-ID: <a9850j$1qc$1@hydrogen.cis.okstate.edu>
Source record: 44827

The output of a PWM or Pulse Width Modulation transmitter
ends up being good old AM. Here is why.

The secret lies in the output filter. It has to be darn
good just like the output tank in a Class C amplifier. The idea
is that the tank rings like a bell at the carrier frequency. The
pulses are loaded with harmonics if not filtered, but the filter
gets rid of the harmonics and produces a sine wave carrier.

If the pulses are more off than on, there isn't much
energy being used to tickle the tank circuit and generate that
ringing carrier.

During maximum output, the pulses are more on than off
and lots of energy is being transfered which makes that tank sing
loudly so to speak.

The modulation signal such as your voice, causes the
pulses to get wider and narrower as the amplitude changes.

I have not got any math in front of me, but I bet the
most efficient pulse width is 50% on and off. This should
transfer the most energy to the tank circuit. Greater than 50%
duty cycles will start looking more like DC to the tank and the
carrier level should go down again.

Anyway, a PWM transmitter ends up producing the exact
same output as a conventional plate or screen modulation-type
transmitter, but very efficiently.

>standard AM receiver using either envelope detection or some other scheme
>see? Is it transparent to the receiver the modulation technique or is it
>chopped at the other end?

It is transparent. You won't hear any difference at all
between a PWM-generated signal and an AM signal generated in any
of the other popular ways to do so.

one other advantage is its ability to generate ANY base power level from
zero to full rated carrier power, with no problems switching high voltages
and currents, and adjusting audio input levels to achieve 100% modulation.

a 10 kW transmitter can be throttled back to 100 watts as easily as it can
to 5 kW

Perhaps another slip of the key, but average power and RMS power are two
different things. In the 1997 ARRL Handbook, chapter 6 has a good
discussion of the difference, including a graph. Other handbook years
will no doubt have the info somewhere.

My last Kenwood was an old '940, probably 10+ years ago. I thought it had a pretty good NB. I owned an FT-1000D for eight years and it could take 20-over 9 atmospheric static down to S2. Also had a Ten Tec Titan that --once equipped with a redesigned NB-- was as good as any I've ever used.

I guess every model is different within each brand.

Gary, A lot of folks don't give RS credit for some of the things they did extremely well. Maybe I'm partial to 'em since I worked in the main office until about 8 years ago.

If you want to hear a DSP filter that'll knock your socks off, listen to the ClearSpeech system... especially the new version that started shipping last August/September.

To my relief, I don't see any mention anywhere in chapter 6 of RMS power. Although an RMS value can be calculated for a power waveform, as it can for any periodic waveform, RMS power has little use. RMS voltage and current are very useful, since they lead to easy calculation of average power(*), which is of great use -- it's the amount of DC power that would cause the same amount of heating.

I'm aware that audio amplifier manufacturers often rate amplifiers as producing so much "RMS power", but as far as I know, that's a calculation of the RMS value of the envelope -- which isn't the RMS value of the power waveform -- and I'm not sure just how it's useful.

Roy Lewallen, W7EL

(*)Average power = Erms^2/R or Irms^2*R

This scheme is used widely in broadcast AM transmitters as the power used in the modulator is much less than the traditional plate modulation scheme.
The supply to the power amplifier of the transmitter can be varied/switched (as in a conventional plate modulator).Instead of varying the supply voltage with a plate transformer it can be switched on and off at a subcarrier rate (say 50 KHz) using switch mode FETs
The duty cycle of the PWM is varied for modulation - 50% for carrier only
The same principle applies in switch mode power supplies and regulators (in fact I have often wondered whether it would be possible to use one of these chips in an AM system - has anyone done this?)
A filter is required to get rid of the subcarrier after the switch or it will appear as sidebands. The result is a varying DC voltage at the modulation rate.
I would be interested in such a system on 3.5 MHz
In fact you could use switch mode FETs for the RF amplifier also at this frequency at about $5 each for the legal limit (150W in Oz)

But then all you need is some sort of decoder, to take the audio tones
and convert them to keying of DC.

Basically, just a filter, and some sort of rectifier. You then use
the output of the rectifier to key some sort of oscillator running
at the frequency of your choice.

You can find plenty of examples of this sort of thing in the ham
magazines over the years. Unless it's all being done in software,
you're going to see the sort of circuitry in anything that decodes
CW to text. Certainly, you saw it a lot when small computers were
new, and everyone wanted to make morse decoders. You also see
this sort of thing as a sort of CW filter. The results seem
mixed, but the idea being that you can filter really heavily
because you won't be listening to the output, and the keyed oscillator
is only the code you want to hear, without the background noise,
fading, and nearby signals.

You don't need to convert to text, you just need the keyed DC
that you will in effect be regenerating by keying your own code
practice oscillator.

That definition - "the amount of DC power that would cause the same amount of heating" is what I was taught as the definition of RMS power, not average power.

Since RMS voltage and current are different from average voltage and current, it stands to reason that the power derived therefrom would be different too.

Isn't it true that:

Peak power = peak V * peak A
RMS power = RMS V * RMS A
Avg power = Avg V * Avg A

Again I refer to chapter 6 of the ARRL handbook for those unclear on the difference between RMS voltage/current and average voltage/current.

I suppose there is such a thing as "average RMS power", but that's something different still.

I've had them do that while installed. Rubbing a slightly damp cloth
across the front of the meter usually cures it (at least for a while).

I've heard of wiping them with one of those anti-static clothes dryer
sheets. Never done it myself, but worth a try.

Just a drop of liquid detergent in the water used to wipe the meter will make the cure last much longer.

As mentioned earlier in this tread ,perhaps the arguments about watt meter accuracy can be curbed by comparing the reading with that of a suitable (calibrated) oscilliscope using a known dummy load.

Michael, that's what I want -- all in software. I don't want to take it off the computer, just convert the tones from one frequency to another.

Simply convert the MP3 to a .wav file and use commonly-available audio manipulation software like Goldwave to shift the pitch of the tone. If the CW rate is not a comfortable speed you can also play with the sampling rate to slow it down or speed it up.

I had that once on a VTVM meter and it about drove me nuts trying to get rid of it. Finally, in desperation, I sprayed the meter with Windex (without wiping) and as the Windex evaporated, it took the static charge with it. Strange but true.

Since then I've often wondered if plain water would have worked but haven't had the guts to try it. :-)

Much to your disappointment the question was not meant as a cheap shot at you or your
meters. By the tone of your post's it would seem that you wish to make your point more by
assertion than by fact and are quick to try and belittle others that may even question your
findings.

Rather than rant about how good the watt meters are that you are using maybe you would like
to share with us what you actually used to measure the power with?

Please keep in mind that most good watt meters can have at least a 10% error of full scale
reading. Using a watt meter with 2500 watts full scale at 1000 watts could be in error by 250
watts. Some meters are not that good.

Most SB200's that I have seen do not put more than 600 watts. Maybe mine and others watt
meters are in error.

SORRY Charlie - I know a cheap shot when one is fired my way - why not just be a man, and admit your
intent, instead of falling back into a tap-dancing routine as a coverup...

> Most SB200's that I have seen do not put more than 600 watts. Maybe
> mine and others watt
> meters are in error.

You know better than *I* do about the quality and accuracy of your own test equipment - so unlike
YOU, I won't profess to judge it unseen, and from a distance... Besides, why automatically assume my
meter - or those of others are reading HIGH? FACT is, the checks I have done with mine against
Waters and Bird wattmeters have indicated MINE read slightly LOW in the areas where there IS a
difference - but usually pretty much dead on on most ranges and readings...

And, I don't mind debate or criticism when it is applied in a constructive and courteous manner -
it's the mindless, juvenile taunts and childish insults that annoy me - sorta like YOURS...

AT this point, it's obvious that constructive communication between us is unlikely - sooooo...

Kerplunk!

MEANWHILE, feel completely free to continue to play to the crowd with witty response...

From: Jim Weir <jim@rst-engr.com>
Message-ID: <ubgr80a1nfcr59@corp.supernews.com>
Source record: 44749

So what I'm hearing, check me if I'm wrong, is that the PWM scheme for AM is necessarily a very narrowband system. That is, if (for example) I wanted to have a PWM system that would cover the entire 2-meter band (all 3% bandwidth of it) then I'd have to retune the "very narrow output filter" every time I changed frequencies an appreciable amount. There would be no such thing as a filter at the output for the entire band, but a hi-Q filter that would need to be tweaked each significant change in frequency.

Now, anybody got a scheme for PWM where a broadband filter could be used and not tuned each time you QSY?

No, that's a property of the average power.

> Since RMS voltage and current are different from average voltage and
> current, it stands to reason that the power derived therefrom would be
> different too.

The average power is, in general, different from RMS power. The average power, as I mentioned in my earlier posting, = Erms^2/R or Irms^2/R. This is the reason we even bother calculating the RMS value of voltage or current -- to make it easy to calculate average power.

> Isn't it true that:
>
> Peak power = peak V * peak A

Yes.

> RMS power = RMS V * RMS A

No. Average power = Vrms * Irms (times the cosine of the angle between V and I if the impedance is reactive).

> Avg power = Avg V * Avg A

No. See above.

> Again I refer to chapter 6 of the ARRL handbook for those unclear on the
> difference between RMS voltage/current and average voltage/current.

I also recommend this source. Notice that nowhere in the chapter does it mention RMS power. I don't believe you'll find RMS power calculated in any text on electricity. Not because it can't be done -- it's well defined and straightforward to calculate -- but it simply isn't useful.

> I suppose there is such a thing as "average RMS power", but that's
> something different still.

You could use this term if you want, but it would be the same as the RMS power. RMS power is a single number, and the average value of a single number is that number.

The average value of any periodic waveform x(t) = 1/T * the integral over a period of x dt.
The RMS value of any periodic waveform x(t) = sqrt(1/T * the integral over a period of x^2 dt)
where T is the period of the waveform
If you look in any text on electrical circuit theory, you'll find the derivation of the equation linking average power to RMS voltage and current.

Don't think it will make a lot of difference using a 6:1 instead of a 4:1
balun for your application.
If you insist on a 6:1 balan , I can refer to 'Building and using Baluns and
Ununs' (practical designs for the experimenter) ,by Jerry Sevick , W2FMI ,
Chapter 5 .

Use Static Guard, it works better. The Endust will only work temporarily.
Sprasy a little on a paper towel and wipe the meter face. You can find Static
Guard in the grocery store.

Ok, if you define average power as Vrms * Irms (as you do above), then
what do you call Vavg * Iavg? To me, that's average power. The other
is RMS power. They are two very different things.

On 14 Apr 2002 00:20:37 GMT, SAM scribbled:
>>Wipe it down with a damp cloth, or better yet use Endust anti-static spray.
>
> Use Static Guard, it works better. The Endust will only work temporarily.
> Sprasy a little on a paper towel and wipe the meter face. You can find Static
> Guard in the grocery store.

yep. Wiping it with a clothes dryer fabric softner
tissue [e.g. Bounce (tm)] will do the trick -- and,
make it smell better, too. :-)

Oh, I agree! But driving (or ovderdriving) such an amp sure offers
little benefit vs. the costs (a new set of tubes) involved.
I never knew that a MLA2500 *could* output 2kw since I never saw it
from mine, even with new tubes. Of course mine is unmodified.

2925. Effects of wide loop BW (was Re: Phase noise (was Re: Hybrid PLL...))

After trying the OP37, it turns out the OP27 was really OK -- I had the wrong value for C1 in the loop filter. The OP27 and OP37 behave identically.

The results with a 3 MHz comparison frequency and 23 kHz loop bandwidth (C1=0.1 uF, C2=0.01 uF, C3=0.01 uF, R2=180 ohms, R3=82 ohms) are:

http://209.95.122.40/jm/hc150khz.gif
http://209.95.122.40/jm/hc110khz.gif
http://209.95.122.40/jm/hc12khz.gif
http://209.95.122.40/jm/hc1200hz.gif

These look VERY good close-in -- the best I've seen. The 200Hz/division plot actually represents the Tek 494's own phase-noise limits, rather than the synthesizer's.

However, the plots at 10 kHz/division and 50 kHz/division show that this approach would, in fact, result in worse adjacent-channel rejection than the existing design. At a 10 kHz offset, the noise with both loops is about -98 dBc/Hz. Beyond that, the original loop with the 2-3 kHz bandwidth (in purple) is dominated by wideband VCO noise, which improves rapidly as the offset increases. Conversely, the high-Fcomp, high-bandwidth loop doesn't really quiet down until reaching offsets of 50-100 kHz from the carrier.

In practical terms, the high-bandwidth loop has substantially worse rejection of DDS noise and spurs. Not only is the loop bandwidth itself wider, but the crystal filter has to be much wider as well to accommodate the extended DDS tuning range associated with the higher Fcomp. (It's possible to design for a narrow loop bandwidth *and* a high Fcomp, but the capacitor values get really large and, at least in some earlier tests I ran, stability suffers.)

It's hard to escape the conclusion that increasing Fcomp beyond a certain point -- 1 MHz or so -- is counterproductive. Keeping the DDS tuning range small is critical for spur performance, and trading wideband noise off for the sake of close-in noise doesn't seem to make sense for conventional voice-bandwidth communications.

You mighta missed THIS post from Bill M back up the thread:

"I've never owned the Dentron but I know two fellas who got them when
they first came out. They both easily did 2200 watts out keydown into a
dummy load, measured with a Bird wattmeter, one was using 110 vac. "

Apparently I am not the ONLY one seeing 2KW or better from these rigs - of course, SOME
critics here
will assert the Bird wattmeter used for the above measurement was probably out of
calibration... Or
the tester too stupid to know how to use it properly...

And yeah, it's possibly true that the output at that power might not be as clean as at lower
levels - but with as much "headroom" as 2KW or better provides, such an amp can CERTAINLY run cool
and clean down at 1.5KW - while one that has to strain at 1200 watts will be operating well into ITS
distortion/nonlinear stage LONG before even reaching the legal limit - so *I* would take the higher
powered option ANY time!

Remember - that's what this thread is ABOUT - the rationale of converting from tubes in an amp that
originally delivered 2KW or better output, to tubes only putting out 800-1200 watts (depending on
whose test methods you prefer) - at a cost in excess of $400...

Source record: 44769

I don't define the average power as Vrms * Irms. Average power is defined the same as the average value of any other waveform. I gave this definition in my previous posting. It just happens that the average power, when calculated using the accepted definition, equals Irms^2 * R or Vrms^2/R. And it also happens that a power waveform with an average power of 50 watts will cause the same amount of heating as a constant (DC) power of 50 watts.

If you're not interested in the mathematics behind these definitions and conclusions, then consult any reputable text, including the ARRL Handbook, read it carefully, and believe what it says. If you are interested in how and why the results are the way they are, maybe the following will help explain it.

The average power is defined as 1/T * the integral over a period of p(t) dt, where p(t) is the instantaneous value of the power, and T is the period. Now p(t) = i(t)^2 * R, where i(t), simplified as i, is the instantateous value of the current, and R the resistance. So the average power is 1/T * the integral over a period of i^2 * R. Assuming R doesn't change with time, we can take R outside the integral to get Pavg = R * 1/T * INT(i^2 dt). I've used INT to mean the integral over a period.

Now look at the definition of RMS current. Irms = sqrt(1/T * INT(i^2 dt)). So Irms^2 = 1/T * INT(i^2 dt). So from the equation for average power, you can see that Pavg = R * Irms^2. The reason Pavg is related to Irms in this way is that P is proportional to I^2. The same holds true for P and V. And this is true for any waveform of V and I -- they don't have to be sine waves.

Now, what do I call Vavg * Iavg? Just that, and nothing more. The relationship of this product to average power depends on the shapes of the waveforms. If V and I are DC, then Vavg * Iavg = Pavg. But for DC, Vavg = Vrms and Iavg = Irms. If V and I are sine waves with zero offset, then both Iavg and Vavg are zero, so their product is zero. Over a period, the voltage or current is positive for half the cycle, and negative for the other half, and it's at the same absolute value for the same length of time. So the average is zero.

Here's a numerical example using sine waves. Let's look at a voltage with peak value of 10 volts (20 volts p-p) and a current with peak value of 10 amps (20 amps p-p), with no DC offset, and both in phase. Mathematically, the both voltage and current can be expressed as 10*cos(omega*t), where omega = 2*pi*frequency. The period T of these waves is 1/f. So the average voltage or current = 1/T * INT(10*cos(omega*t) dt) = f/omega * (10 * sin(omega*t)) evaluated over a period = zero, as I mentioned.

Sometimes, "average" voltage or current is used to mean the average of the absolute value of the waveform. This is often used when describing the response of analog meters, since the meter movement mechanically averages the rectified (absolute value) voltage. So I'll include a calculation using this meaning. To get the average of the absolute value, we can evaluate the integral over the positive half cycle and double the result. This gives 40*f/omega = 40/(2*pi) = 6.37 volts or amps. Squaring this we get 40.53 watts.

It's well known that the RMS value of the voltage or current is about 0.7071 times the peak value, or 7.071 for our example voltage or current. Let's see if we can get that by directly using the definition of RMS. Vrms = sqrt(1/T * INT(v^2 dt)) = sqrt(1/T * INT(100*cos^2(omega*t) dt)) = 10 * sqrt(1/2T * (t + sin(2*omega*t)/(2*omega))) evaluated over a period = 10 * sqrt(f/2 * 1/f) = 10 * sqrt(1/2) = 7.071 volts. The RMS value of the current in our example is then of course also 7.071 amps. The product of Vrms and Irms is 50 watts.

Now let's calculate the average power directly, from the definition. Pavg = 1/T * INT(p dt) = 1/T * INT(vi dt) = 1/T * INT(100*cos^2(omega*t) dt) = 100 * 1/2T * (t + sin(2*omega*t)/(2*omega)) evaluated over a period = 100 * f/2 * 1/f = 50 watts. So the average power = Irms * Vrms, not Iavg * Vavg (which is zero), or the product of the averages of the absolute values of the voltage and current waveforms (which is 40.53 watts).

Just out of curiosity, let's see what the RMS power is. It's sqrt(1/T * INT(p^2 dt)) = sqrt(1/T * INT(v^2 * i^2 dt)) = sqrt(1/T * INT(10000*cos^4(omega*t) dt)) = 100 * sqrt(1/T * (3*t/8 + [sin 2*omega*t term + sin 4*omega*t term]) evaluated over a period. The last two terms weren't written out becuase they evaluate to zero anyway. Continuing, Prms = 100 * sqrt(f * 3/(8*f)) = 100 * sqrt(3/8) = 61.24 watts. Interesting, but of no real use. And you can see it's not equal to Irms * Vrms.

I mentioned some time ago in this newsgroup -- and got a certain amount of flak for it -- that I was a lousy student. I'd appreciate it very much if those of you who really paid attention in freshman calculus and circuit analysis would look over my work and correct any errors you find.

This has been a lot more interesting, although nearly as tedious, as doing my taxes. But that's what I really need to be doing, so I'll get back to work now.

Geez, I feel stoopid now. In the late 70s when guys were gobbling up
the Dentrons I never heard of one putting out less than 2kw key down.
Both my friends who had them were very active DXers and the tubes were
cooked in less than two years. One guy sprang for retubing, the other
bought another amp. They knew they were abusing the amp...at the time
nobody knew how long they would (or would not) last.
I don't question at all that the MLA-2500 is (was) not beefy enough to
do this kind of power on any regular basis. Shoot, the pwr xfmr is
about the size of the one for my Galaxy 5 transceiver which is good for

about 200 w out with fresh tubes. And I remember both these guys replacing other parts which had 'melted down'. Putting the Dentron in the context of what I was used to seeing in that era, I thought at the time that it was very cheaply built....certainly not up to par with MY homebrew pair of 4-400As that only put out 600-800w.
That being said, jazzing it up with different tubes to run 2kw+ out isn't such a good idea anyway but the headroom would be nice.

I'll take your word for the advanced math. My forte is English.

It seems clear that if:

Ppeak = Vpeak * Ipeak,

then it follows that

Prms = Vrms * Irms and

Pavg = Vavg * Iavg,

since power of any kind is the product of the V and I of that same kind,
regardless of what kind it is - peak, DC, RMS, whatever, as long as you
are careful to be consistent. To define the power terms any other way
is illogical and inconsistent.

Note that I'm talking resistive power only; reactive circuitry is
another discussion.

I think I would be satisfied if someone can explain why the three
formulas above are incorrect. Why power of one kind isn't derived from
the V and I of the same kind. That's my whole point.

I'd want to do a linearity test to check that out. As for me, I've
always been able to do anything I wanted or needed with mine at the
lower power level, things such as work VK0IR on a nearly dead 20 meter
CW band where they couldn't copy me barefoot.

Bingo! I hate to keep jumping into this thread since I never owned one, but that was the FIX of the era now that you remind me! That might explain the disparity between the 2kw+ ones and the measly 1.4kw examples.

2935. Updated one transistor receiver 'Radio Shack Special'...

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-14 07:11:07 UTC
From: braincambre500@yahoo.com
Message-ID: <85a87c6c.0204132311.202cb9cf@posting.google.com>
Source record: 44777

Hello all,

I just updated and improved the one transistor FM receiver. I have
been constantly working on it to make it the best I can. I had stray
hand capacitance when operating the tuning capacitor...now with the
whole PCB, front and back, covered in copper...the 'stray went away'!

Also, I am just using a 10 inch antenna, bringing in 24 stations in my
area.

I wanted to let anyone know that this is a marvalous little week-end
project.

...do go and see the updated 'Radio Shack Special', at:

http://braincambre500.freeservers.com

I want to thank everyone for their time in
reading
my request.

Sincerely,

Patrick Cambre

Nor can you knock the cars.

If you've seen those old Chevy taxi's, many have over a million miles on
the clock!

They don't get maintained at your drive-in Autolube.

The planes are something else.

Carried over from the Cruschev era.

Tupolov's or whatever they call them can however run on anything, just
like the Lada cars back home in Russia.

You can take the tail fin off and she'll still stay up:-)

On Sat, 13 Apr 2002 17:51:43 -0700, Bill Turner <w7ti@dslextreme.com>
wrote:

>Ok, if you define average power as Vrms * Irms (as you do above),

The average power is a very useful entity e.g. when measuring the
mechanical power applied to a generator or the heat dissipated in a
resistor.

Apparently only in English is this cumbersome rms (root-mean-square)
expression used with voltages or currents to tell the equivalent DC
voltage or current to produce the same heating of the resistor.

In other languages expressions like tehollisarvo (Finnish),
effektivvï¿½rde (Swedish), Effectivwert (German), valeur effectiv
(French) etc. are all referring to the effective value of the
equivalent DC circuit.

For a sinusoidal, these are calculated P = Vrms*Irms*cos(phi), in
which phi is the angle between voltage and current and the unit is
[W]. Don't mix this with the apparent power Vrms*Irms, which is
measured in [VA] regardless of the angle between voltage and current.
The apparent power can be large, but the effective value can be 0, if
the angle between the voltage and current is +/-90 degrees.

>then what do you call Vavg * Iavg?

What would you call Vpeak*Iavg*4.7 or Vavg * Iavg / 2 ?

Since all these do not represent any usable physical quantity, why
should they have a specific name ?

One might also ask, what is Vavg or Iavg for an AC circuit. You could
very well argue that they are both 0 for a true sinusoidal AC
waveform. Only when the waveform is distorted with even order
harmonics, there will be a small DC component, which you could call
Vavg :-).

Iavg is a useful quantity for _DC_ measurements, e.g. when a load
current is varying and you want to measure how much charge has been
extracted from a battery (Q = Iavg * t).

============
The fact that your antenna is made of 300 Ohms tv ribbon ,does not
necessarily mean its impedance at the frequencies used is 300 Ohms.
Suggest you get hold of an antenna analyser of the MFJ or Autek variety (eg
borrow from a friendly fellow Ham) and determine the impedance. Only then
you can define your needs for any balun /impedance transformer. But measure
with the antenna in its operating position.
I am sure you will be very surprised when measuring the actual impedance
directly with one of the above or similar instruments.
Good luck

Oil caps (no PCBs) are definitely preferred ; problem might be finding the space in existing cabinet.
Peter Dahl -El Paso -TX usually has a large variety and stock of these HV caps ; another possible source is Surplus Sales of Nebraska (usually the expensive option)

John
What happens if you use a crystal (or equivalent) reference for the loop at the two different frequencies?
The DDS should be nearly as good as its crystal reference as far as random phase noise goes, with the main problem being coherent phase and amplitude spurs. However none of these appear on the plots you have shown. It should be possible to separate out the effect of the DDS/reference from the effect of the loop.

If it is a small antenna and not far above ground, its actual radiation resistance is likely to be quite low, ie much less than 300 ohms. In fact you may need the balun with the high impedance on the transmitter side as the impedance might only be 10-20 ohms
It would be best to measure the impedance by some method.
Say cut/tune the antenna to resonance (use a GDO or similar) and measure the impedance using a 1:1 and 4:1 balun to the antenna using a noise bridge. You could then work out the best scheme to match to your transmitter.

Look under caps ... mentions the Dentron specifically

CP-140 SET OF 6 MATCHED 140mF 450VDC COMPUTER GRADE CAPACITORS W/ MOUNTING SCREWS The CP-140 is a matched set of 6 140mF 450VDC computer grade capacitors by Cornell-Dubilier. Also included are the mounting screws with lock washers. These are perfect for HV power supplies and amp builders. They can also be used to replace bad caps in Dentron and other amplifiers. Capacitor size is 3-3/8" x 1-3/8". The cost for the set is $48, USA & Canada shipping included. Sales tax for Indiana residents is $2.40.

Quite correct, Vavg for a complete cycle of a sine wave would be zero.

I wouldn't take hold of it, however. :-)

Interesting antenna. Never seen that one before.
The author doesn't make any mention of the feedpoint impedance at
resonance and mentions the tuner and xfmr/balun in the context of
widening the bandwidth. Although he's using 300 ohm feeder I don't
think you can assume the feedpoint impedance is 300 ohms.
I'm at a loss as to what to suggest in this case apart from getting or
building a tuner. I'll defer to the sharper brains on the subject.
-Bill

At low power like a Pixie, you can simply wind a transformer on an FT50-43 or even an FT37-43. I successfully did something similar to use a random loop at powers up to 30 watts.

What I did, and I have no idea how valid it is, was calculated the primary to present 50 ohms of impedance at the operating frequency. I may have quite a bit of reactance in this lashup, though, I'm using a tuner after it. The transformer makes it a bit of an easier job for the tuner. Works quite well to get me on 80 where I don't have the space for a proper antenna. I understand, though, that the theoretical basis is pretty shaky.

Given that you have a pretty much fixed configuration, you might consider measuring the antenna as suggested by others, then calculating a pi network to do the match. A little bit of extra harmonic reduction wouldn't hurt with a Pixie.

..

Source record: 44791

Thanks, George. It wasn't so much a slip of the key as a lax moment. I haven't used these design prinicples in years, and I was last doing class C amps and cared mainly about average power.

It's been interesting to read all the follow-on postings this has led to. My compliments to Roy especially for his discussion of peak/rms/average issues, which can really be dealt with clearly only if you use the mathematics (the true definitions) in addition to the words. It's a bit of a shame that we can't represent it well in ASCII, though (how *would* one do an integral sign :-)

... Rich

And what does a degaussing coil have to do with STATIC electricity???

I wouldn't suggest to anybody to pass a meter by a degaussing coil and its strong MAGENTIC field....!!!!

Why not put a small bit of liquid dishwasher detergent on your fingertips and gently wash the face of the meter, followed by a dampened paper towel... It's always worked fine for me.

I don't really understand the point requiring the data, if it is
exactly like 6146B, you may look yourself at
http://frank.nostalgiaair.org/sheets6.html

I haven't had any of those Kenwood rigs using the device, but believe
it is just a question of different neutralization setting between
S2001A and 6146B. It might of course, give you higher price when
selling to dummies if you could show a data sheet.

Gary - KJ6Q schrieb in Nachricht ...
>Remember - that's what this thread is ABOUT - the rationale of converting from tubes in an amp that
>originally delivered 2KW or better output, to tubes only putting out 800-1200 watts (depending on
>whose test methods you prefer) - at a cost in excess of $400...

Well, above is NOT what this thread is ABOUT-
originally NI4L was looking for the original qst-article (title),
when you jumped in to declare that this conversion make no sense...

Again, there is no reason the russian tubes do less output then the 8875s, of course same mode used.
Anyhow there plate dissipation value is already bigger the 8875...
Under keydown condition (steady carrier) I do not have to worry about distortion at all, so this test would be fine to find out how much power is coming out of an original MLA2500 when measured with an oscilloscope into 50 ohm dummyload.
To make shure everything has settled, measurement should start after 1 minute
keydown.

As mentioned in previous mails I repaired and modified a couple of MLA2500s and also MLA1200s, so I am familiar with the Dentron power-supplies and the capability of the 8875 tubes.
I never saw more then 700 Watts from one 8875 !!

This thread is about conversion of the MLA2500 to tubes available at good prices.
Conversion will work fine with tubes like GU74b, Gi7b, 4CX800, 4CX400, TBL2/500 .
Limiting factor is the ht transformer and the pi-circuit components.

carl
i dont know the lay out of the SUV but i would suggest mounting it where the
ashtray is unless you smoke then you can go with one of those radios that has
a removable face plate then mount the radio under the seat and the faceplate on
the dash somewhere
as for an antenna a 5/8 wave on a magmount on the roof would be good

One nice idea I saw with the Icom-207H (a dual-band rig) was to mount the head up by the mirror. They have a long cable available and the wire is easily hidden in the molding, plus the 207's head is quite small. There's a picture at http://www.qsl.net/w8kea. The guy who did it made a bracket so the molding screws could hold it in place.

The plots made at exactly 1 GHz don't show any DDS spurs, either with or without the crystal filter. It's not hard to find frequencies where spurs are still visible, though, as the spur-search zipfiles on the site show. You really wouldn't want to run a synthesizer like this without the narrowband DDS filter in place.

Some interesting plots with the wideband (23 kHz calculated BW) loop using different reference sources:

http://209.95.122.40/jm/uref.gif (50 kHz/division)
http://209.95.122.40/jm/wref.gif (10 khz/division)
http://209.95.122.40/jm/nref.gif (2 kHz/division)

The graph colors correspond to the following reference sources, each driving the LT1016 reference-buffer comparator at 21.407 MHz, -2 dBm:

Blue = AD9854 DDS clocked at 100 MHz with HP8662A synthesizer, fDDS = 21.407 MHz through 25 kHz 4-pole crystal filter and MAV-11 post-filter amplifier

Purple = HP8662A (high-quality synthesizer)

Green = HP8640B (free-running cavity oscillator with ECL divider chain)

Red = HP8656A (lower-end HP synthesizer)

Interestingly, the MAV-11 following the crystal filter contributes a noticeable amount of noise (a dB or so) to the wideband plot outside the filter's bandwidth. When I built this prototype, I should have put it between the DDS and the filter. (It's not used in the PCB version at all.)

"r.crowley" <rcrowley7@xprt.net> wrote:
>Is this method used anywhere? With modern digital circuitry, it seems
>almost easier to do than traditional methods of amplitude modulation.
Aye, there's the rub. With a single exception, PWM in HF transmission results in traditional amplitude modulation (Heising, to be precise) where the PWM--or PDM--circuitry is used to take a higher DC voltage and convert it to a constant voltage (carrier) or a variable voltage (audio) with a DC (carrier) average value. The single exception was an RF Pulse Width system where the width of the RF pulse driving the RF amplifiers resulted in convention AM although at unacceptable conversion efficiencies at carrier.

PWM (as the term in used here) is simply an efficient way to get from AC (50 or 60 Hz) to DC to variable DC to RF. The first patent was in the 30's and uses a switching element in series with a supply to develop voltage for the anode. Two patents issued in the 60's, the first to Collins (Forrest Cummings) and the second to Gates (Hilmer Swanson). The Collins Patent put the RF tube anode at DC ground and applied a modulated voltage to the cathode. The Gates Patent applied the HV supply directly to the RF tube anode and placed the PWM modulator in the cathode return. In both cases, stored energy in the modulator was reduced and efficiency improved. Later, Harris (Ed Westenhaver/Hilmer Swanson) patented a method using four PWM modulators in parallel, each at a quadrant of a four-phase clock giving, in effect, a switching frequency four times higher than the clock. Later, Continental Electronics patented a method that let the clock frequency be determined by the amount of high-frequency audio information while reverting to the original concept. Subsequently ABB (later Thomcast and now Thales) and Continental Electronics both patented systems using step-pulse modulators that, rather than use switches in parallel, seriesed either 32 or 48 switches. This lowers the switching frequency of each switch to less than 2kHz while leaving the change frequency clock at 70 kHz.

None of these system are suitable for amateur use since, in practice, they result in an unwanted carrier and unwanted sideband being formed rather than the more (power and spectrum) efficient mode of single sideband transmission. In fact, all of the HF transmitters that now use PWM have EER (Envelope Elimination and Restoration) capability that allows single sideband to be transmitted at high efficiencies. SSB use on the HF bands is limited only by the primitive receivers used for general shortwave (HF) reception. A short tutorial on EER is at: http://rfwireless.rell.com/pdfs/AN_629_D.pdf

Almost every transmitter manufacturer, receiver manufacturer and international broadcaster is moving to adopt DRM (Digital Radio Mondiale), a system of digital transmission for HF use. This mode delivers high-fidelity stereo transmission in a limited spectrum space. Each element of the signal uses perceptual audio encoding (similar to MP3's) and retransmits the same information several times so that multipath and selective fading do not result in loss of signal lock/demodulation. Step-pulse (PWM) Modulators and EER are used to generate the digital signal efficiently as the peak to average power can exceed 10 dB (10:1 power ratio.) Frequency agile transmitters for HF service still use vacuum tube in (at least) the PA stage because of the difficulties in combining solid-state amplifiers over the required three octaves of frequency coverage. More information on DRM can be found at: http://www.drm.org/

Hello All,
i'm looking for Informations about the old Icom CI-IV Paralell Bus.
I have read the Thread of an old Posting from sm6pxj but the Infos are not what i want. The Reason is: I have an old Icom IC271H without UX14 and i want to Design a Replacement for the UX14 with an Atmel ATmega. So i'm looking for Informations about the Paralell Bus. Does anybody have a Descrition of the EX-309 Interface? (This was the old paralell Interface for this Rig) I need the following Infos:
How works the internal paralell Bus?
Why can i connect the Bus to a Microcontroller?
What Commands are used?
I hope i get Help here.
I use this because i will use this RIG as a Receiver for AO 40 operations as Receiver and want to controll it via my Computer.
Thanks.

A most interesting post.

I seem to remember reading among all my class-E reference material that
Raab or Sokal certainly wrote papers if not hold patents regarding EER.

Regards your final paragraph I think you will find at least one US based
HF broadcast transmitter manufacturer who does in fact use a solid state
PA.

http://www.omnitronix-inc.com/sw.htm

However coverage is limited to 3-6MHz!

I just remembered that both Continental and HCJB are also in there with
PLL 'all solid state' HF AM broadcast rigs.

I want one:-)

Thanks for that John.
It is interesting that the 8640 (presumably running unlocked) gave the best results. The cavity oscillator should have the best phase noise of the various devices and I understand that dividers contribute relatively little noise. Thinking about the whole problem I think the critical figures for the reference would be its frequency and relative phase noise at that freq - the two could be combined to give a "figure of merit". Even if the comparison frequerncy is low (say only a few KHz) the reference phase noise is divided down and then multiplied up again. So the critical ratio is probably clock freq to output freq. Anyway that subject is probably done to death and we wont gain much more there!

Hi Jason,
I tried to build a DCTL antenna for 80 m from a 300 ohm TV twinlead,
hanging outside, the bottom was only several feet above ground. The
module of the input impedance (measured by Autek) was approx. 150 ohm
at resonance, increasing to both "sides of frequency".
A 1:3 balun should be fine - make a transformer with 1:1,7 turns
ratio.
Unfortunately, my TX is not QRV, so I have no on-band experience with
this antenna.

About to get my first rig. I was licensed back in February and have been studying the 'build-it-yourself' websites'. My question is this, every example has used aluminum tubing for the beams, except the copper j-pole I saw. Can I not use copper instead of aluminum on the beams? Is it not as good? The reason is I have a LOT of copper tubing left over from some plumbing work I helped with. I just thought that maybe I could use it for my 2 meter beam instead of having to buy the aluminum stuff. Any thoughts? Thank you for your time.

Depending on the diameter of the copper tubing , if you intend using 1/4 to 3/8inch dia copper tubing it might not stiff enough and sag .This would not happen with alu tubing. Also copper tubing would require a protective coating,especially in an urban environment with the air contaminated with sulphur compounds.
Moreover copper is heavier.

I don't deal with the sub-compacts much, I have an Excursion. ;^) Anyway, on the bottom of the dash is a small indentation. Just below the pocket in the dash to the right of the steering wheel. Brake controllers are often mounted there. I mounted my radio there and mounted the brake controller to another bracket connected to the radio bracket. I then use a 2m magmount that looks like a cell phone antenna. I can hit all the repeaters I need in about a 50 mile radius. The newer magmounts have a layer of mylar over the magnet, so it does not damage the vehicle. My has worked quite well, and I enjoy it quite a bit. Good luck.

With copper, weight is probably the biggest factor to consider. Apart from that, as one post said you would want to coat the out side with something to protect the surface. I have a homebrew "super" J-pole and it works great. I just used spray paint on my j-pole to protect the surface and works fine (Take care to mask off where the adjusting contacts are at.). With a yagi for 2 meters and a small RS TV rotor no problem. I use a small rotor from RS for an aluminum 10 meter 3 element yagi and it's been there for years.
There is a design for a copper yagi using the "j-pole" design as the driven element. Interesting design.
If I recall it was 3 element design. The yagi-j-pole may be a neat design to experiment with. Good luck.

Copper has a lower resistance than aluminum and should work a little
better. It is not generally used for antennas because it is heavier,
cost more, and can have a corrosion problem if not treated with
something to protect it from the weather.

Agree with other comments on the NG - all good advice. My thought is to keep the copper tubing for building splitters/combiners when you have made more than one identical antenna and want to use them together to give you more gain / direction etc.
Have lots of fun building them all

A 12 volt lamp will work fine, but burn slightly dimmer...although they will
last longer! Radio Shack carries them.

The way I read the data sheets on the GI7BT
that 650 hour life is running full tilt pulse at almost 3000 Mcps.
Pulse is 9 kV and 7 A for 63 kW peak input.
Efficiency is only 10% but that's still a 6 kW pulse out.
A cathode that can handle 7A pulses should last a long time
running 50% duty cycle and 550 mA....

I'm about 1/2 done with a single in a SB200 for 50 Mcps.
I'll be surprised if I don't see 600W RMS out for ICAS operation.

Gain is a bit more than 2 X that of the 572B so an HF SB200
conversion should give full output when driven with the newer
50W max output transceivers.

Hi Wayne..
Try this URL..also has a downloadable file for the diagram. The designer calls it a "Jagi". Looks to be a "plumbers delight".
Let me know if you build it and how it perfroms. Very interesting design IMHO...Jim

There's no way you'd be able to notice any improvement due to the
resistivity difference. The only significant difference is mechanical.

Roy Lewallen, W7EL

Suggest you replace these lamps with a LED + suitable dropping resistor.
That will solve the bulb problems (probably) forever.
Good Luck.

From: donrm@soco.agilent.com
Message-ID: <1018911298.158587@cswreg.cos.agilent.com>
Source record: 44734

I posted this 4-13-00 with no answer; perhaps someone
may have come across the article by this time...

I'm still looking for help steering me to an article I saw
for a solid state synchroscope as used for synchronizing
two alternators - only instead of the usual two lite
bulbs, this one utilized a crystal oscillator comparing
60 Hz emergency alternator power and displaying it on
LEDs arranged in a circle that rotated with phase dif-
ference.

The original article was for synchronizing a field day
alternator to a 60 Hz crystal controlled timebase.

I've searched the yearly index for Ham Radio and Com-
munications Quarterly in addition to keyword search
on the ARRL member site. Not recalling the name of
the article complicates things considerably. Perhaps
I saw it in Wireless World.

Anyone come across it and remember where I saw it?

From: kalmichael@yahoo.com.au
Message-ID: <b6ae557e.0204151657.5d31d4aa@posting.google.com>
Source record: 44736

I've have a couple of interesting projects that call for IRF510s,
including the wideband HF amplifiers mentioned here. I have easy
access to some IRF520s: could these be substituted for the 510s?

I have the data sheets, and the devices seem pretty much the same
except that the 520 can handle twice the drain current and has a lower
switch-on resistance. Does this mean that they are simply a higher
power version of the 510, and would plug straight in in the their
place?

Still learning, assistance appreciated.
Michael.

Look under caps ... mentions the Dentron specifically

CP-140 SET OF 6 MATCHED 140mF 450VDC COMPUTER GRADE CAPACITORS W/ MOUNTING SCREWS The CP-140 is a matched set of 6 140mF 450VDC computer grade capacitors by Cornell-Dubilier. Also included are the mounting screws with lock washers. These are perfect for HV power supplies and amp builders. They can also be used to replace bad caps in Dentron and other amplifiers. Capacitor size is 3-3/8" x 1-3/8". The cost for the set is $48, USA & Canada shipping included. Sales tax for Indiana residents is $2.40.

Comet and Diamond Antenna make mounts that attach nicely to the side lip of the hatch door. I've got two mounted near the top, on either side, and they work nicely. This area is black trim on my '97 so there is no paint to mar. Also, this mounting location is fine when you open the hatch, because the antenna lays out horizontally along the roof line, a bit outboard so it clears the roof.

Careful.. seen several rigs with melted lamp holders due to lamps getting too hot. Try the replacement.. if it gets HOTT.. then put a resistor in series. Melted Lamp holders can make a mess of the front panel..

Nope. You didn't look quite far enough down on the data sheets. The killer spec for these devices is the capacitance, which is very high and, like any diode reverse capacitance, nonlinear. The tricky part of designing a rig using a VMOS device is dealing with this. The 520 is basically two 510 chips wired in parallel. This gives you twice the current handling capability, half the on resistance, and. . . there ain't no free lunch. . . twice the capacitance. In general, a project designed for a 510 can't use a 520, and usually can't easily be redesigned to handle one.

Mike:

The ARRL Radio Amateur's Handbook has a 160-10 linear amp using a pair of IRF-510's. I have the 2001 edition and it probably appears in others as well. With a 28 V power supply, 1 watt in gives 40 watts out (at least, but higher on some frequencies).

Just a note-if these backlights are actually "wafers", then they are almost certainly NOT LED devices, but EL(ElectroLumenesent)-the spelling is a bit "off", but you can figure out what I mean.
These have VERY different characteristics than an LED device.
High voltage, at VERY low current is used for EL panels.

Not so at all. In the 50's I built a channel 2 three element TV yagi
(plumbers delight) and had it up for 7 years. HD copper is pretty tough
stuff. I wouldn't have any trepidations in using it at least down thru 6
meters, but it isn't going to be light.

back in the early 80's, we were putting radios in new LTD squad cars

the city insisted on having the antennas mounted ON the light
bars.............well, there was about 3 extra feet of light bar cable left
over, so the install guy made a loop around the 'computer' (actually, the
ignition module) on the left inner fender

all was well until a car was going balls-to-the-wall to an accident one day,
the driver hit the button on the mike, and the ignition died, just like
you'd turned the key off

only on one channel of the radio, and only at wide-open throttle

but boy, did we have fun 'diagnosing' the trouble.....we must have
used 5 tanks of gas 'trying to duplicate the problem'.....

I noted you mentioned the three-octave range.

Shows you how dumb I am.

I thought 'frequency agile' meant PLL tuned rather than rock-bound if
only in this case coverage is rather narrow.

I better get back to selling Dinky Toy transmitters.

A friend has some radios for sale. Which of these is easiest to convert to other VHF-lo frequencies or possibly up to 6m? By easiest I mean it can be changed by dip switch/computer reprogramming/PROM swap but if not, whichever one has the most available parts and is easiest to convert with a minimum of retuning. I am assuming the two tube units would be the most difficult to work with. Are either of the Motorolas reprogrammable with a new prom or computer upload?

If you know anything about these radios please let me know as all I have are model numbers. They are all set up for at least two channels on 46 Mhz.

RCA MBA19MAII 2 chan mobile $150
GE Master-II Model LB1-44506 2 chan 100W mobile $150 w/manual
Motorola Mitrex 75V 4 chan w/ remote head and manual $225
Motorola Twin V model T61GJD-3A-PH50 2 chan 100 W mobile runs off of 6/12V $50
Comco 580-HA 2 chan tube base &extra parts $50
Comco 2 chan tube mobile $25

Thank you!!

Frequency Electronics has some info for you. The first place to check
for this kind of information is the manufacturer's web site.
If you go to their web site you'll find a 12 page PDF brochure that
includes technical specifications and pin outs for the connector.
It also lists options, but option 58 is not among them.

The brochure includes basic description of rubidium frequency
standards and would be of use to anyone that would like to learn
a little about them.

>Comco 2 chan tube mobile $25
>

These are all crystal controlled radios (I am not familiar with the
RCA, but most likely it is the same vintage). That is, to set them to
a new channel frequency requires installing new crystals (a pair, one
for receive and one for transmit) for each channel. After installing
the crystals it will be necessary to retune the radio. This will require
a signal generator, 50 ua meter, RF power meter and some tuning tools.
It is also a good idea to have the manual with tuning instructions.

The Mitrek should be fairly easy to convert to 6M. The tube models
will probably require some modification, i.e., changing some tuning
capacitors.

BTW, some of the prices look kind of high.

Not sure about US copper, but in UK copper fittings and pipe work fine
for most frequencies where you would use tube. We have a "Z" grade
which is hard drawn and very thin walled, not sure of the weight (
versus ali) but usable down to 10m with "soldered endfed" connectors.
the "microbore" 8mm Z grade is excellent for 2m.

Carl:
You might consider something innovative as I had to do on a lease vehicle. I have a 99 Explorer (Limited) and there is NO spare space , so I made up two inverted "J"
brackets; bolted them to the mobile mount bracket, mounted the bracket to the bottom of the radio and hung it from the center console(open the console, hang it on and close the cover). No holes to drill, easily reachable/readable and when I leave the vehicle for an extended period, I open the console; raise the radio up and slide it under the seat. Works for me! If you're interested, e-mail me direct and I'll tell you about the "no holes visible" roof mount I made! G.I. ingenuity!

Hell for a 2m beam copper would be fine and dandy.

Copper, especially FREE copper, is wonderful stuff. It does oxidize pretty quickly.

Pedro,
That was a version made specially for Motorola and FE will not release the information. A bit of poking around inside will probably tell you what to do if you are brave enough :-)

One of the people selling these on eBay did include the connections though, so the information is out there.

I have one of the older bigger Efratom units fitted in a Racal 9475 standard and that was pretty easy to sort out...

I rember seeing schematics for crystal testers that were nothing but a
single transistor oscillator. It would oscillate at the fundamental
frequency of the crystal. Is this what you have?

It's a bit late to mention this, but Stanford Research advertises the
PRS10 Rubidium Frequency Standard for $1495, quantity 1.

This months QST has an article about grid dip oscillators. One can be
used to test crystals.

No it's not Jim. I have something with two grounded base transistors,
one on the input and one on the output, with the crystal or crystal
filter placed between them. The circuit did not oscillate, but was a
way of loading the crystal or crystal filter with the proper impedances.
There was a pot on both the input and the output to the crystal or
crystal filter.

Thanks and 73

Henry

with an RF-detector connected to the output this circuit will operate
as xtal tester

Repost

Some years ago xtal testers seem to be interesting projects, and
several circuits were described in the magazines for handy tester you
could bring with you when you were looking for surplus xtals, probably
FT243 then.

Below is shown a simplified circuit for an xtal tester, this is just
connected to my counter, and some xtals has been tested since the
tuning capacitor is 150pF and will give some indication of xtal tuning
ranges.
It seems that xtals made for colour burst oscillators may be pulled
more than others, but otherwise xtals are pullable by a degree which
rises with frequency, and channel xtals for VHF sets seem not less
pullable than other xtals. The circuit is just an ordinary XO, not
VCXO, but still xtals may have the required pull range for certain
applications.

3046. AM Modulation Distortion

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-18 01:21:15 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <946sbu8rm0lk7lcricarg1tcd3gifhap3h@4ax.com>
Source record: 44690

I've been tinkering with a low power (100 mW) synthesized AM broadcast band transmitter. Synthesizer is working and now I've got the transmitter and modulator section going.

I'm seeing a strange distortion when I look at the modulated envelope. There is a time shift between the positive envelope peak and the negative envelope peak. It can be seen easily with a modulating sine wave signal of 10 KHz. There's around 7 to 8 microseconds delta between the top envelope peak and the bottom envelope peak. This peak shift corresponds to around 30 degrees phase shift at 10 KHz. At 1 KHz, the result is a tolerable signal, but the distortion becomes more objectionable as the modulating frequency increases.

I'm seeing this both on the real circuit and on the computer model that I've constructed with MultiSim 2001, so I'm inclined to view the problem as inherent, not caused by some component parasitics.

My suspicions center around the 2N7000's behavior at the bottom crests of the modulating waveform. It's acting differently with, say, < 1 volt or so VDD at the bottom of the modulation cycle.

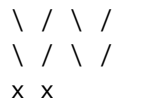
A quick description of the circuit is a square wave VCO output (5 volts peak), drives a 2N7000 MOSFET through a 74HC00 gate used as a buffer. Output of 2N7000 goes to a five pole low pass filter to turn the square wave into sine wave. Test RF frequency is 1000 KHz, but same problem is seen with other frequencies.

Modulation is via a series emitter follower NPN (TIP31) transistor, driven by a Norton amp (LM3900). RF is kept out of the modulator with a series pair of 330 uH chokes and 4700 pF bypass caps. (I'm going to have to alter this a bit, as these values do roll off the 10 KHz audio a bit.)

With no modulation, output of the emitter follower is set to 5.5 volts. Modulation swings take this up to 10.5 volts and down to 0.5 volts. Feedback to the Norton amp is from the emitter of the modulation transistor. Supply voltage is 15 volts, to provide some headroom for the modulation transistor.

I can send a JPG of the output waveform or a schematic of the transmitter if it will be of assistance. Here's an ASCII art version of the output envelope:

```
-a- -a-
/ \ / \
/ \ / \
/ \_ / \
```



the negative peak (x) occurs at about 7 to 8 microseconds later than
the positive peak (a).

You're circuit description doesn't match too well, but perhaps you are thinking of an article from January 1990 QST. The article is by Doug DeMaw intitled "A Tester for Crystal F, Q and R". The article is reprinted in the current ARRL publication "W1FB Design Notebook". Hope this helps.

Regards,

Lee

I drive a 4-Runner.

The control head is mounded on the console with double sided tape for the
bracket.
The RF deck, which is mounted on an Aluminum plate goes under the seat.
I was going to put some velcro on the bottom to keep it from sliding, but
never found a need.

I would first check the measurement equipment and procedure. I have seen this too but can't quite recall what caused it; the subject wave was fine but it looked that way on the oscilloscope.

Check the probe compensation. Also, make sure the probe isn't loading the circuit or the oscilloscope isn't being driven into distortion.

I presume Your Computer model (MultiSim2001) is working
by means of Volterra-series, and as this phenomenon is seen
also in the simulation that it is indeed a real phenomenon,
and not a mesurement set-up prolem (which is the first guess).

What You are watching is "AM/PM- phenomenon". How hard do
You drive the modulator? (not enough information available in
Your question). - You'll need a substansial "back-off", so
that You during the entire modulation cycle is within a
perfectly (or very near perfectly) linear part of the curve.

In short: If You alter the DC biasing of Your modulator and
at the same time lower the LF drive level, what happends?
You will have to live with bad efficency. This has been the
truth for A.M. systems since the dawn of time. You need that
irritating idle "no-use" idle current.

Or, the problem might be in the final amp. of Your system.
Try the same as above! Higher efficiency than 20% should not
be expected, if You want a "good behaviour".

But, as input data is insufficient, the problem might be
elsewhere. And, what has AM broadcast with amateur radio to do?
Rgrds,
"I.R Baboon"
